PRODUCT FOUNDATION

1.1. Product Definition

1.2. Product Objective

1.3. Target Customer

1.4. Problem Definition

1.5. Product Outcomes

1.1 Product Definition

PRODUCT DEFINITION

Owómidé MVP is a Collaborative AI Pricing Workspace for mid-to-large businesses operating in dynamic, competitive and price-sensitive emerging economies.

It provides a shared environment where businesses and their pricing stakeholders can plan, design, create, analyse, review, refine, execute, monitor and manage pricing work across products, services, categories, channels, locations and other relevant pricing scopes.

At its core, the workspace functions as a collaborative AI-native pricing builder.

Users bring the products, services or other items they need to price into a common working environment; define what they are trying to achieve; construct and document pricing strategies, rules, logic and proposals; define the conditions and parameters of the pricing approach; reference applicable organisational Guardrails; analyse the financial implications of different pricing choices; collaborate with the stakeholders involved; and move the resulting pricing work from creation through review, the applicable organisational decision path, execution and subsequent monitoring, all with AI embedded throughout the process.

The workspace acts as the operational environment for pricing work rather than merely a repository of final prices or an approval system.

It brings together the information, reasoning, workflows, participants and controls involved in developing and managing pricing work so that teams no longer have to assemble the process across disconnected spreadsheets, ERP exports, messaging applications, email threads, documents and meetings.

AI is embedded throughout the workspace as an assisting participant.

Within the permissions and information available to the invoking user, AI can support activities such as:

- analysing pricing information;
- identifying risks or inconsistencies;
- drafting or refining pricing work;
- summarising inputs and discussions;
- assisting with calculations and scenarios;
- explaining pricing implications;
- retrieving relevant historical context;

- supporting strategy development;
- helping users navigate complex pricing tasks.

AI assistance remains attributable and subject to human control.

The workspace supports collaborative pricing work across its lifecycle, including:

- organising products, services and other entities being priced;
- viewing and working with relevant pricing and economic information;
- creating and managing pricing initiatives, proposals, strategies, rules and related pricing work;
- defining pricing objectives, assumptions, parameters and conditions while referencing applicable organisational Guardrails;
- evaluating unit economics and the implications of proposed pricing actions;
- collaborating through shared context, comments, evidence, assignments and contributions;
- maintaining versions of evolving pricing work;
- routing work through appropriate review and organisational decision processes;
- controlling actions through roles, permissions, authority levels and organisational policies;
- executing or recording authorised pricing actions through the mechanisms available in the MVP;
- monitoring the status and progression of active pricing work;
- preserving the rationale, inputs, changes, organisational decision records and outcomes associated with pricing work;
- making historical pricing knowledge searchable and reusable;
- providing AI assistance across relevant parts of the workflow.

The MVP is not simply to digitise pricing approvals. It is to provide businesses and their pricing stakeholders with a dedicated collaborative working environment in which developing, coordinating and managing pricing work becomes more economically informed, efficient, structured, visible, intelligent, reusable and controllable.

1.2 Product Objective

PRODUCT OBJECTIVE

The objective of the Owómidé MVP is to make the Collaborative AI Pricing Workspace the **primary working environment in which businesses and their pricing stakeholders carry out and coordinate pricing work**.

Instead of pricing work being fragmented across spreadsheets, ERP exports, email, messaging applications, meetings, documents and individual knowledge, the MVP brings the relevant pricing context, analysis, logic, participants, workflows, controls and history into one AI-native workspace.

The MVP should enable a pricing team to move a piece of pricing work from an initial need, trigger or objective through analysis, construction, collaboration, review, the applicable organisational decision path, execution and monitoring without repeatedly reconstructing the process across disconnected tools.

The objective is not merely to digitise the existing manual process. The product should improve how pricing work itself is performed by making it more structured, context-rich, collaborative, intelligent, traceable and reusable.

The objective is to **enable a pricing team to collaboratively turn a pricing need, objective or market/business trigger into a well-informed, controlled and executable pricing action, while preserving the context, logic, collaboration and history behind that work.**

A pricing need may begin through:

- a supplier or product cost change;
- margin deterioration;
- a competitor price movement;
- a promotion or campaign;
- a scheduled pricing review;
- a new product or service launch;
- inventory conditions requiring markdown or repricing;
- a commercial opportunity;
- a stakeholder request;
- creation or revision of a pricing strategy or rule;
- an external market or business condition change;
- a management objective, mandate or guardrail.

The core pricing lifecycle is:

Understand context → Frame objective → Develop pricing approach → Analyse implications → Collaborate → Apply organisational controls → Decide → Execute → Monitor → Preserve and reuse knowledge

The MVP should enable teams to:

1. **Understand the pricing context**
   Bring together the product, current price, cost information, commercial information, previous decisions, supporting evidence and other available inputs required to understand the pricing situation.
2. **Frame the pricing objective**
   Establish what the pricing work is intended to accomplish, what it affects, the assumptions involved and the constraints within which the team must operate.
3. **Develop the pricing approach**
   Create and refine the proposed pricing action, strategy, rule or logic, including relevant parameters, conditions and calculations while referencing applicable organisational Guardrails.
4. **Analyse the implications**
   Evaluate unit economics, financial consequences, risks, trade-offs, alternatives and other available evidence.
5. **Collaborate around the work**
   Allow relevant stakeholders to contribute information, evidence, comments, revisions and expertise while working from the same pricing context.
6. **Apply organisational control**
   Ensure pricing work respects roles, authority levels, applicable Guardrails, item-level Approval or Policy Authorisation requirements, and organisational policies.
7. **Reach and execute a decision**
   Progress the work through required review and the applicable organisational decision path, then translate valid execution authority into an executable or recorded pricing action.
8. **Preserve the decision context**
   Retain the reasoning, information, versions, participants, organisational decision records, changes and actions associated with the pricing decision.

9. **Monitor the work after decision**
   Maintain visibility into implementation, status and relevant subsequent outcomes rather than treating the organisational decision as the end of the process.
10. **Reuse organisational pricing knowledge**
    Make previous pricing work, rationale, decisions, strategies and patterns available as context for future pricing activity.

Role of AI

Owómidé is AI-native rather than a conventional workflow product with AI added as a secondary feature.

AI should operate across the pricing workflow rather than exist only as a standalone chatbot.

Where appropriate and permitted, AI should help users:

- understand pricing information;
- construct pricing work;
- analyse implications;
- surface relevant context;
- identify inconsistencies and risks;
- synthesise stakeholder input;
- explore alternatives;
- explain calculations and decisions;
- retrieve organisational pricing knowledge;
- reduce repetitive analytical and coordination work.

Human users retain governance control over consequential pricing work in the MVP.

AI assists the pricing process but does not independently acquire Approval or Policy Authorisation authority, create execution authority, circumvent organisational controls or perform actions outside the permissions and context available to the invoking user.

Where Policy Authorisation is enabled, authority derives from the organisation's configured non-AI policy mechanism.

Product Success at the Job Level

The MVP succeeds at its core job when a real pricing team can use Owómidé as the primary environment for completing actual pricing work from initiation to execution and monitoring,

with substantially less dependence on disconnected spreadsheets, messages, email chains and undocumented institutional knowledge.

The critical test is not whether users can simply create or approve a price.

It is whether a meaningful unit of real pricing work can **live, progress and remain intelligible inside Owómidé from beginning to end**.

1.3 Target Customer

TARGET CUSTOMER

The Owómidé MVP is built for **mid-to-large businesses operating in emerging economies** whose pricing activities are sufficiently complex, frequent, distributed or commercially important that manual and semi-automated pricing processes create material operational, financial or competitive problems.

The customer is the organisation.

Pricing teams and pricing-adjacent functions are the primary users through whom the organisation receives value.

Owómidé is particularly relevant where pricing involves multiple products, services, locations, channels, stakeholder groups, pricing rules or recurring pricing decisions, and where the business currently coordinates this work through combinations of spreadsheets, ERP systems, email, messaging applications, meetings and other disconnected tools.

Initial Segment Priority

The MVP should remain horizontally capable of supporting pricing work across industries while product development and go-to-market activity initially concentrate on segments for which current research provides the strongest evidence.

Primary initial customer segments

- Multi-location retail chains
- Multi-vendor marketplaces
- High-catalogue commerce and e-commerce businesses
- Mid-to-large manufacturing businesses managing product portfolios

For commerce-oriented organisations, strong-fit characteristics include managing approximately 500 or more SKUs and operating across two or more sales channels.

Secondary initial customer segments

- Mid-to-large accommodation and hospitality businesses managing rates across locations or distribution channels
- Mid-to-large transportation and mobility businesses managing dynamic fares or rates across routes, locations or channels

These segments guide initial product validation and commercial focus. They do not permanently restrict Owómidé to these industries.

Primary User Population

The principal users are people who participate directly or indirectly in organisational pricing work.

Direct pricing users

- Pricing managers
- Pricing analysts
- Category managers
- Revenue managers
- Commercial pricing specialists
- Other employees whose primary responsibility includes analysing, constructing or managing prices

Indirect pricing users

- Finance
- Commercial leadership
- Sales
- Procurement
- Operations
- Category and brand leadership
- Executives
- Compliance or audit
- Marketplace or vendor management
- Pricing operations and implementation personnel

The MVP must therefore support pricing as a **cross-functional organisational workflow**, rather than assume that pricing is performed by a single specialist or department.

Operating Context

Strong-fit customer environments commonly involve:

- manual or semi-automated pricing processes;

- several systems or communication channels involved in pricing work;
- relevant pricing information distributed across people and tools;
- multiple stakeholders contributing to or controlling pricing decisions;
- pricing activity across multiple products, categories, locations or channels;
- decisions requiring financial, commercial or operational judgement;
- organisational control over who can propose, modify, approve or execute pricing activity;
- difficulty retrieving historical pricing rationale and decision context;
- market, cost, demand, competitive or operational conditions changing faster than current pricing processes can respond;
- pricing mistakes, delays or inconsistencies creating measurable margin, revenue, operational or competitive consequences.

The MVP should accommodate organisations at different levels of pricing maturity.

Owómidé should not require a dedicated pricing department, sophisticated pricing software or fully digitised pricing operations as a prerequisite for adoption.

Geographic Context

Owómidé is built for businesses operating across emerging economies.

The broader target includes emerging and frontier economies across:

- Africa
- Latin America
- the Middle East
- Southeast Asia

Initial validation and commercial execution are concentrated in:

- Nigeria
- Kenya
- South Africa

These are priority launch and learning markets, not the permanent geographic boundary of the product.

The MVP should anticipate differences in things like:

- currencies and currency volatility;
- taxation and pricing conventions;
- organisational structures;
- connectivity and infrastructure reliability;
- channel fragmentation;
- pricing maturity;
- approval practices;
- available business systems;
- data availability and quality;
- regulatory environments.

The MVP should solve a common pricing-work problem across emerging economies while allowing each organisation's local operating context to shape its configuration.

1.4 Problem Definition

PROBLEM DEFINITION

“**In emerging economies, mid-to-large businesses lose 10–20% of margins, miss 30–38% of revenue opportunities, and waste 15+ hours weekly because fragmented, manual workflows lack real-time market visibility in environments where nearly 90% of commerce occurs offline and is fast-moving.**”

The problem is not simply that businesses use spreadsheets, email or manual approval processes.

The deeper issue is that pricing is a continuous, distributed and cross-functional business process, while most organisations still manage it as a collection of disconnected activities.

A single pricing action can depend on things like:

- cost information;
- margins;
- competitor prices;
- demand;
- inventory;
- supplier conditions;
- customer behaviour;
- commercial objectives;
- regulatory constraints;
- historical decisions;
- management judgement.

These inputs are often owned by different teams and stored across different systems.

The organisation must repeatedly bring these pieces together before it can make, approve and execute a pricing decision.

1. Fragmented Pricing Workflows

Pricing work is commonly distributed across ERP systems, spreadsheets, BI dashboards, email, messaging applications, meetings, internal tools and individual working methods.

Each tool may perform its own function, but the pricing work itself does not necessarily exist as one continuous process.

This forces teams to manually move information and decisions between systems and stakeholders throughout the pricing lifecycle.

2. Pricing Depends on Distributed Organisational Knowledge

Pricing is rarely controlled by one person or department.

Different functions contribute different parts of the decision:

- Finance contributes cost, margin and financial implications.
- Sales contributes customer behaviour, demand and commercial feedback.
- Pricing, revenue or category teams structure and analyse pricing work.
- Procurement contributes supplier and input-cost information.
- Marketing contributes market, promotion and demand context.
- Operations contributes inventory and execution realities.
- Commercial leadership determines strategic direction.
- Management provides authority for consequential decisions.
- Legal or compliance functions may impose regulatory constraints.
- Operational teams and systems execute the resulting pricing action.

The challenge is not simply getting people to collaborate.

The organisation must coordinate specialised responsibilities while maintaining one coherent pricing context.

3. Pricing Teams Spend Too Much Time Assembling the Decision

A significant part of pricing work is spent gathering, checking, reconciling and interpreting information before the actual decision can be made.

Users may need to obtain:

- cost information from finance;
- sales performance from ERP systems;
- competitor information from market visits;
- supplier updates from procurement;
- customer feedback from sales;
- historical information from previous spreadsheets or reports.

Even when the information exists somewhere in the organisation, assembling it into usable pricing context remains largely manual.

This creates repeated analytical and coordination work every time pricing work is initiated.

4. Market Conditions Move Faster Than Pricing Processes

Pricing decisions in emerging economies can be exposed to fast-changing conditions including:

- FX movements;
- inflation;
- input and supplier costs;
- logistics costs;
- competitor pricing;
- customer purchasing power;
- demand changes;
- inventory conditions;
- promotions;
- government policy;
- taxation;
- regulation;
- seasonal behaviour;
- distribution conditions;
- market availability.

These conditions can change continuously while internal pricing processes may still require multiple handoffs, reviews, meetings and approvals.

This creates a mismatch between the speed of the market and the speed of the organisation's pricing response.

5. Offline Market Structure Creates an Information Gap

A significant proportion of commercial activity in emerging economies occurs outside fully digitised channels.

Competitor prices, distributor behaviour, open-market prices, supplier movements and other commercially relevant signals may require:

- manual field research;
- store visits;
- phone calls;
- supplier relationships;
- informal market networks.

Businesses may therefore have strong internal ERP and BI capabilities while still lacking timely visibility into what is happening outside their own systems.

Pricing decisions can consequently depend on information that is incomplete or already stale by the time it reaches the decision-maker.

6. Pricing Analysis Requires Continuous Synthesis

The difficult part of pricing is often not calculating a percentage or changing a price field.

The harder task is determining how multiple variables should influence the decision at the same time.

Businesses may need to balance:

- profitability against competitiveness;
- margin against volume;
- market share against short-term profit;
- customer affordability against cost inflation;
- stock clearance against margin protection;
- growth targets against market conditions;
- commercial urgency against governance requirements.

Pricing therefore requires continuous synthesis of financial, market, operational and strategic information.

Where this synthesis remains manual, the quality and speed of decisions become heavily dependent on individual experience.

7. Cross-Functional Coordination Creates Decision Latency

Pricing work frequently moves between several people before execution.

One stakeholder performs analysis. Another challenges the assumptions. Finance recalculates the economics. Sales provides market feedback. Commercial leadership reviews the recommendation. Management provides approval. Another team implements the resulting decision.

Changes at one stage can force earlier stages to be repeated.

This creates back-and-forth coordination, duplicated work, follow-ups and waiting time that extend the pricing cycle.

8. Decision Context Is Easily Lost Between Stages

As pricing work moves between people and systems, organisations can lose continuity around:

- why the pricing work started;
- which information was used;
- which assumptions were made;
- what alternatives were considered;
- what changed during review;
- which version is current;
- who contributed to the decision;
- what was approved;
- what was ultimately implemented.

The resulting price may remain in an ERP while the reasoning that produced it remains distributed across spreadsheets, messages, emails and individual knowledge.

9. Pricing Errors Become Margin and Revenue Problems

When costs change without prices being reviewed quickly enough, businesses can continue operating with economically incorrect prices.

When market conditions move faster than the organisation responds, the business can remain overpriced, underpriced or commercially misaligned.

When pricing analysis does not contain the full cost or commercial context, a decision that initially appears profitable can become loss-making once logistics, marketing, supplier or other costs are considered.

These failures connect operational pricing weakness directly to margin leakage and missed revenue opportunities.

10. Organisations Lack a Continuous Pricing Operating Environment

Most businesses already have tools for individual parts of the pricing process.

The missing layer is the environment connecting the work together.

The organisation needs a place where pricing work can retain its:

- context;
- data;
- analysis;
- assumptions;
- strategy;
- contributors;
- workflow;
- decisions;
- approvals;
- execution state;
- history.

Without that continuity, every pricing initiative becomes another coordination exercise.

MVP Problem Scope

The MVP focuses on reducing the fragmentation, manual coordination and decision friction involved in how mid-to-large businesses perform pricing work by providing a continuous AI-native workspace for planning, analysing, constructing, collaborating on, governing, executing, monitoring and preserving pricing work.

1.5 Product Outcome

PRODUCT OUTCOME

The MVP should be judged by whether it materially improves how businesses perform pricing work, not by whether individual features are used.

Success means Owómidé becomes a working environment through which real pricing activity can be completed more efficiently, intelligently and controllably than through the organisation's existing process.

1. Business Outcomes

The MVP should help businesses:

- reduce avoidable margin leakage caused by delayed, incorrect or poorly informed pricing actions;
- capture more revenue opportunities by responding faster to pricing needs and changing commercial conditions;
- reduce the employee time consumed by manual pricing analysis, coordination, follow-ups and administrative work;
- improve visibility and control over pricing activity across the organisation;
- reduce pricing errors and economically unsafe decisions;
- improve the consistency and quality of pricing decisions.

The broader validated business problem establishes margin loss, missed revenue opportunities and 15+ hours of weekly pricing-related waste as the economic context against which these outcomes should ultimately be evaluated.

2. Pricing Workflow Outcomes

The MVP should enable a meaningful unit of pricing work to progress through Owómidé from initiation to completion without the core workflow depending on disconnected spreadsheets, email chains or messaging threads.

A successful workflow should allow users to:

- establish the pricing objective and scope;
- bring together the relevant pricing context;
- develop and analyse the pricing approach;
- collaborate with required stakeholders;

- review and revise the work;
- apply relevant guardrails and organisational controls;
- complete the applicable organisational decision path and establish valid execution authority;
- record or complete execution;
- monitor the resulting state;
- retain the complete history and rationale.

The intended outcome is a measurable reduction in pricing cycle time, coordination effort and unnecessary back-and-forth.

3. Decision Quality Outcomes

The MVP should improve the quality of pricing decisions by ensuring that users can evaluate relevant financial, commercial and operational implications before execution.

Users should be able to understand:

- the current pricing position;
- the proposed pricing action;
- the economic impact of that action;
- relevant assumptions and constraints;
- important risks or guardrail breaches;
- alternative scenarios where applicable;
- the reasoning supporting the final decision.

The product should reduce the likelihood that consequential pricing actions are taken without sufficient context or economic understanding.

4. Collaboration and Organisational Alignment Outcomes

The MVP should create one shared pricing context for the people involved in a pricing workflow.

Success means stakeholders can understand:

- what pricing work is active;
- what stage it is currently in;
- who is responsible for each required action;
- what information and assumptions are being used;

- what has changed;
- what input is required from them;
- what has already been reviewed or decided, including Approval or Policy Authorisation where applicable;
- what happens next.

The product should reduce dependence on manual status updates, repeated explanations and stakeholder chasing.

5. Governance and Control Outcomes

Pricing work should remain governed according to the organisation's defined roles, permissions, authority, Guardrails and applicable organisational decision requirements.

Success means:

- users can perform only actions they are authorised to perform;
- applicable Approval or Policy Authorisation requirements cannot be bypassed;
- Approval or Policy Authorisation authority remains bound to the exact controlled Pricing Proposal version against which it was established;
- material changes must not inherit Approval or Policy Authorisation authority from an earlier Pricing Proposal version;
- pricing guardrails are applied consistently;
- sensitive pricing and cost information respects access restrictions;
- consequential actions remain attributable to specific users;
- the history of the pricing workflow remains auditable.

Governance should provide control without unnecessarily slowing down routine pricing work.

6. AI Outcomes

AI should create measurable value inside the pricing workflow rather than exist as a decorative feature.

Successful AI assistance should reduce the effort required to:

- understand pricing context;
- analyse pricing information;
- construct or refine pricing work;
- identify risks and inconsistencies;

- evaluate scenarios and alternatives;
- summarise complex pricing activity;
- retrieve relevant historical information;
- prepare work for review or the applicable organisational decision path.

AI output must remain explainable within the context of the user's task, constrained by the user's permissions and subject to organisational Governance. AI must not independently create Approval, Policy Authorisation or execution authority.

7. Pricing Knowledge Outcomes

Pricing work completed in Owómidé should create reusable organisational knowledge.

The business should be able to retrieve and understand previous pricing work without reconstructing it from individual employees, emails or old spreadsheets.

Historical records should preserve relevant:

- objectives;
- context;
- inputs;
- assumptions;
- analysis;
- versions;
- stakeholder contributions;
- decisions;
- organisational decision records, including Approval and Policy Authorisation;
- execution records;
- outcomes.

This should progressively reduce dependence on individual institutional memory.

8. MVP Activation Definition

An organisation is meaningfully activated when it completes its **first real structured pricing workflow in Owómidé using actual organisational pricing data**.

The workflow should progress through the relevant stages required by that organisation, including analysis, collaboration, required review, completion of the applicable organisational decision path, and a completed or recorded pricing action.

Completing a tutorial, creating a workspace, importing data or generating an AI response does not constitute activation.

9. MVP Success Metrics

The MVP should measure success using a combination of adoption, workflow, efficiency and business-impact indicators.

Primary product indicators

- Time from first login to first completed real pricing workflow
- Pricing workflows completed per account
- Pricing cycle time
- Time saved on manual pricing work and coordination
- Weekly active organisations
- Weekly active pricing users
- Multi-stakeholder participation in pricing workflows
- Percentage of initiated pricing workflows successfully completed
- Audit trail completeness
- Frequency of repeat pricing activity in Owómidé

Decision and control indicators

- Number and rate of guardrail breaches detected before execution
- Number of pricing actions requiring revision before organisational decision
- Organisational decision turnaround time, including item-level Approval where applicable
- Frequency of pricing errors or reversals
- Percentage of completed pricing work with preserved rationale and supporting context

AI indicators

- Percentage of pricing workflows where AI assistance is used
- AI-assisted tasks accepted, modified or rejected by users
- Reduction in time spent on AI-supported pricing activities
- Repeat use of AI assistance within active accounts

Business-impact indicators

Where customer data permits, the MVP should track:

- margin improvement or avoided margin loss;
- revenue impact associated with pricing actions;
- market-response speed;
- pricing-related labour hours saved;
- return on investment from using Owómidé.

These measures should be evaluated against each customer's baseline rather than assuming identical results across organisations.

10. MVP Success Definition

The MVP is successful when target businesses repeatedly use Owómidé to complete real pricing work and demonstrate that the workspace produces a materially better pricing process than their previous operating method.

At minimum, success requires evidence that Owómidé:

1. becomes part of the organisation's recurring pricing workflow;
2. reduces manual coordination and fragmented pricing work;
3. shortens the time required to move pricing work from initiation to execution;
4. improves visibility into pricing context, responsibilities and decision state;
5. provides useful AI assistance during real pricing work;
6. preserves reliable pricing history and accountability;
7. improves organisational control over pricing decisions; and
8. produces measurable operational or economic value sufficient for customers to continue paying for the product.

Feature completion alone does not constitute MVP success. The MVP succeeds only when customers repeatedly use it for consequential pricing work and prefer that operating model to the process it replaces.

2. Product Scope

2
PRODUCT SCOPE

2.1. Product Model

2.2. Product Lifecycle

2.3. Capability Architecture

2.4. Scope Boundary

2.1 Product Model

PRODUCT MODEL

The Owómidé MVP should organise pricing work around a small set of connected product objects rather than treating individual screens, spreadsheets or approval requests as isolated activities.

1. Organisation Workspace

The **Organisation Workspace** is the top-level environment for a customer organisation.

It contains the organisation's:

- users and teams;
- products, services and other priceable entities;
- pricing initiatives;
- organisational pricing policies;
- roles and permissions;
- pricing guardrails;
- workflow configurations;
- pricing history and organisational knowledge.

Users operate inside the same organisational environment while seeing and performing only the actions permitted by their assigned authority and scope.

2. Pricing Initiative

The **Pricing Initiative** is the primary unit of pricing work in the MVP.

It represents a defined piece of pricing work being undertaken for a specific business purpose.

Examples include:

- repricing products following a cost increase;
- reviewing a category's pricing;
- launching a new product;
- designing a promotion;
- clearing ageing inventory;
- responding to a competitor movement;

- revising a pricing strategy;
- changing prices for a customer, region or channel;
- performing a scheduled price review.

A Pricing Initiative should contain the complete context required to understand and progress that work from initiation through completion.

It can include:

- objective and rationale;
- affected pricing scope;
- structured Pricing Context and supporting Evidence;
- assumptions;
- pricing strategy or logic;
- calculations and analysis;
- scenarios;
- stakeholder contributions;
- proposals;
- versions;
- organisational decision records, including Approval and Policy Authorisation records;
- execution records;
- monitoring information;
- complete activity history.

This becomes the persistent container that prevents pricing context from being lost as work moves between people and stages.

3. Pricing Scope

Every Pricing Initiative must define what the pricing work applies to.

Pricing Scope represents the Priceable Entities and pricing context to which the pricing work applies.

A Pricing Scope must contain one or more Priceable Entities defined in DATA-001.

Priceable Entities may be included in scope through:

- direct selection of individual Priceable Entities;

- selection of a supported organisational grouping, such as a category or product group, that resolves to multiple Priceable Entities;
- another supported scope-selection mechanism that resolves to identifiable Priceable Entities.

The Pricing Scope may additionally be qualified by applicable pricing dimensions such as:

- location;
- region;
- channel;
- customer group;
- business unit;
- vendor;
- price list;
- other organisation-defined pricing dimensions.

Categories, product groups and pricing dimensions may therefore determine which Priceable Entities or pricing contexts are included in scope, but they must not be treated as Priceable Entities solely because they are used for scope selection.

Where a grouping selector is used, the system must be able to determine which Priceable Entities are included by that selector.

The same Pricing Initiative may apply to multiple Priceable Entities and multiple pricing-dimension combinations where the pricing action is logically managed as one piece of work.

At any consequential decision point, the applicable Pricing Scope must be sufficiently resolved to determine the exact Priceable Entities and pricing dimensions affected by the proposed action.

4. Pricing Strategy and Logic

The workspace must allow users to express **how the pricing decision should work**.

This includes:

- pricing objective;
- strategy;
- calculation logic;

- rules;
- conditions;
- parameters;
- assumptions;
- thresholds;
- constraints;
- references to applicable organisational guardrails.

Organisational Guardrails remain Governance-owned controls. Pricing Strategy and Logic may reference applicable Guardrails but must not independently create, redefine or own them.

The MVP should represent this logic in a human-readable format so authorised stakeholders can understand, review and challenge it without requiring technical expertise.

For example:

Increase selling price by 8% across the selected products while maintaining gross margin above 15%.

More complex pricing logic can combine multiple conditions and rules where required.

5. Pricing Analysis and Scenarios

Pricing Initiatives should support analysis of the economic and commercial implications of proposed actions.

Users should be able to evaluate relevant information such as:

- Current Price or another explicitly identified pricing baseline;
- proposed price;
- Applicable Unit Cost and relevant cost basis, where required;
- gross margin;
- markup;
- gross profit;
- price change percentage;
- alternative pricing scenarios;
- expected or manually entered business implications.

A **Scenario** represents an alternative pricing approach that can be evaluated before the team commits to a proposal.

Scenarios remain exploratory until explicitly selected or incorporated into the active pricing work.

6. Pricing Proposal

A **Pricing Proposal** is a specific proposed action produced from the work inside a Pricing Initiative.

It represents what the team is proposing to do, not the entire pricing initiative itself.

A proposal should contain the exact:

- affected scope;
- Current Price or other explicitly identified pricing baseline used;
- proposed pricing state;
- supporting rationale;
- assumptions;
- relevant analysis;
- applicable Guardrail evaluation and configured behavioural treatment;
- applicable organisational decision requirements.

Once a Draft Pricing Proposal is formally submitted into the applicable organisational decision path, that same Proposal version is frozen as the controlled decision snapshot.

Submission does not create a new Proposal version solely because the Proposal entered the decision path.

A material change after submission must create a new controlled Proposal version rather than silently modifying the version previously submitted for approval or policy authorisation.

7. Workflow

Each Pricing Initiative progresses through the canonical Pricing Initiative lifecycle defined in Section 2.2.

The canonical lifecycle is:

Initiated → In Development → In Review → Awaiting Approval → Ready for Execution → Implemented → Monitoring → Completed

Workflow governs how pricing work progresses through the applicable review, organisational decision and execution-readiness requirements within that canonical lifecycle.

Workflow may determine or coordinate:

- required reviewer actions within the canonical In Review stage;
- responsible participants;
- review completion requirements;
- the applicable organisational decision path;
- item-level approval where applicable;
- policy-authorisation routing where applicable;
- approval sequence and routing;
- Changes Requested and revision loops;
- bounded escalation;
- authorised delegation where supported;
- execution-readiness gating;
- attributable workflow history.

Organisational differences must be represented through the bounded Workflow Configuration Profile model defined in Section 2.4 and Section 3.8.

Workflow configuration must not create alternative Pricing Initiative lifecycle states, arbitrary workflow graphs or unrestricted user-defined workflow automation.

Pricing Proposal decision states and approval progress must remain separate from Pricing Initiative lifecycle state.

8. Approval Record

An **Approval Record** captures an authorised user's formal decision on a specific proposal version.

It should preserve:

- approver;
- decision;
- timestamp;

- proposal version;
- comments or conditions;
- authority under which the action was taken.

Approvals must attach to the exact version reviewed.

A material change after Approval must create a new controlled Pricing Proposal version and complete the applicable organisational decision requirements before new execution authority can be established. The earlier Approval must remain bound only to the Proposal version against which it was made.

9. Policy Authorisation Record

A Policy Authorisation Record captures execution authority established for an exact controlled Pricing Proposal version through the organisation's configured policy-authorisation mechanism rather than through item-level human Approval.

It should preserve, where applicable:

- exact Pricing Proposal version;
- applicable organisational policy;
- qualification conditions and evaluation result;
- submitting or invoking user and relevant authority context;
- relevant Guardrail configuration and evaluation;
- authorisation timestamp.

Policy Authorisation must remain distinguishable from human Approval and must bind only to the exact controlled Proposal version evaluated.

A materially changed Proposal must complete a new policy-authorisation evaluation or other applicable organisational decision path before receiving new execution authority.

10. Execution Record

An Execution Record captures what happened after a Pricing Proposal received valid execution authority through approval or policy authorisation.

It should establish:

- what pricing action received execution authority;

- what was actually implemented;
- who implemented or recorded it;
- when implementation occurred;
- implementation status;
- any implementation notes or exceptions.

The MVP therefore preserves continuity between **decision and execution**, even where the actual operational price update occurs outside Owómidé.

11. Evidence and Collaboration

Pricing work should support contextual collaboration directly around the relevant initiative, proposal, rule, scenario or other pricing object.

This can include:

- comments;
- supporting documents;
- links;
- manually entered observations;
- stakeholder input;
- decisions;
- mentions and assignments.

Collaboration should remain attached to the pricing work it relates to rather than becoming a disconnected general conversation.

12. Activity and Audit History

Every consequential action should contribute to a persistent chronological history.

The history should capture relevant events such as:

- creation;
- edits;
- version changes;
- comments;
- assignments;
- submissions;
- reviews;

- Approval and Policy Authorisation events;
- rejections;
- guardrail events;
- execution;
- status changes.

This provides both operational visibility and historical accountability.

13. AI Participation

AI operates across these product objects rather than existing as an isolated system.

AI may assist with a Pricing Initiative, strategy, analysis, scenario, proposal, collaboration thread or historical context.

AI-generated work must:

- remain attributable as AI-assisted;
- operate within the invoking user's permissions;
- use only information the user is authorised to access;
- remain reviewable by human users;
- require explicit authorised-user action before AI-generated content is applied to consequential pricing work.

AI does not independently approve or authorise consequential pricing actions.

Core Product Relationship

The core MVP relationship is:

Organisation Workspace
→ Pricing Initiative
→ Pricing Scope + Context + Strategy/Logic + Analysis/Scenarios
→ Pricing Proposal
→ Workflow and Collaboration
→ Organisational Decision Authority
→ Execution
→ Monitoring and Historical Record

The Pricing Initiative is the connective object that holds this lifecycle together.

Organisational Decision Authority may result from item-level Approval or valid Policy Authorisation according to the applicable controlled decision path.

2.2 Product Lifecycle

PRODUCT LIFECYCLE

Pricing Initiative Lifecycle

A Pricing Initiative should represent the complete lifecycle of a piece of pricing work from initiation through execution, monitoring and closure.

The lifecycle must track the **business state of the pricing work**, not merely the screen a user is currently viewing.

1. Initiated

A Pricing Initiative begins when a pricing need, opportunity, request or trigger is formally created in Owómidé.

At minimum, the initiative should establish:

- title;
- pricing objective or reason;
- initiative type;
- owner;
- pricing scope;
- urgency;
- relevant collaborators;
- initial supporting context.

The initiative then moves into active development.

2. In Development

This is the main working state.

Users can:

- gather and attach relevant context;
- develop pricing strategy and logic;
- define assumptions and parameters;
- perform calculations and analysis;
- create scenarios;

- assess unit economics;
- collaborate with stakeholders;
- use AI assistance;
- construct the proposed pricing action.

An initiative may remain in this state through multiple iterations.

3. In Review

When the pricing work is sufficiently developed, it can move into review.

Relevant stakeholders can:

- inspect the pricing context;
- review assumptions and analysis;
- comment;
- request clarification;
- identify issues;
- recommend changes;
- confirm readiness for formal decision-making.

Review is distinct from the organisational decision that may subsequently establish Approved or Authorised Within Policy status.

If material changes are required, the initiative returns to In Development.

4. Awaiting Approval

Once applicable review and Proposal-readiness requirements are satisfied, the Pricing Initiative enters Awaiting Approval while the current Pricing Proposal progresses through the applicable organisational decision path.

The organisational decision path may be:

- item-level human approval; or
- configured policy authorisation where that capability is enabled and the Proposal qualifies.

At entry into the organisational decision path:

- the current Draft Pricing Proposal version is frozen as the controlled decision snapshot;
- the exact affected Pricing Scope is resolved;
- the applicable organisational decision path is identified;
- relevant Workflow and Governance requirements are established;
- applicable Guardrail configuration and authoritative Guardrail evaluation are preserved as part of the decision context;
- the submitting user and submission timestamp are preserved;
- subsequent material changes require a new controlled Proposal version.

Where item-level approval applies, the controlled Proposal version progresses from Draft to Awaiting Approval and the required approvers and approval sequence are determined through the applicable Workflow and Governance rules.

Where configured policy authorisation applies, the same controlled Proposal version is evaluated against the applicable policy-authorisation requirements.

A Proposal validly qualifying for policy authorisation may progress from Draft to Authorised Within Policy without being represented as having received human Approval.

The applicable Workflow may vary through the supported Workflow Configuration Profile, but it must remain within the canonical Pricing Initiative lifecycle and bounded decision models defined by this PRD.

5. Decision Gate

The applicable organisational decision path can produce four relevant outcomes.

Approved
The required authority has approved the submitted proposal version.

Changes Requested
The proposal requires modification and returns to development or review. Any revised submission becomes a new version.

Rejected
The submitted proposal is rejected. The initiative may be revised and resubmitted or closed without execution.

Authorised Within Policy

Where the organisation has explicitly enabled predefined within-guardrail autonomy, qualifying pricing work may proceed without item-level approval. The system records the action as authorised under the applicable policy, not as an approval.

No user may approve their own submitted pricing proposal.

6. Ready for Execution

Once a proposal has received all required approvals, or has been validly authorised within policy, it becomes eligible for execution.

At this stage the initiative should clearly show:

- authorised pricing action;
- exact pricing proposal version providing execution authority;
- effective date;
- implementation owner;
- execution instructions;
- affected pricing scope;
- any conditions attached to the decision.

An unapproved or unauthorised pricing action cannot be marked as implemented.

7. Implemented

The implementation owner records that the authorised pricing action has been implemented.

The execution record should capture:

- what was implemented;
- implementation date and time;
- implementing user;
- actual implemented price or pricing state;
- implementation notes;
- deviations from the authorised decision baseline, if any.

Where the implemented state differs materially from the authorised decision baseline, the discrepancy must remain visible rather than silently replacing or reinterpreting the authorised Pricing Proposal version.

8. Monitoring

After implementation, the initiative can enter a monitoring state.

Users should be able to record or assess relevant outcomes such as:

- sales or transaction movement;
- margin impact;
- revenue impact;
- volume changes;
- commercial feedback;
- customer response;
- observed issues;
- whether the pricing objective was achieved.

Monitoring requirements may differ by initiative type and organisation.

9. Completed

A Pricing Initiative becomes completed when:

- the required pricing work has finished;
- the final decision is known;
- execution status is resolved;
- required monitoring or outcome information has been recorded where applicable.

Completion makes the initiative part of the organisation's permanent pricing history.

Completed initiatives remain searchable and available as context for future pricing work.

10. Supporting Lifecycle States

The MVP should also support:

On Hold
Work is temporarily paused without being cancelled. On Hold is a temporary supporting state and does not change the underlying lifecycle stage from which the initiative was paused.

Cancelled
The Pricing Initiative is intentionally terminated before completion, with the reason recorded.

Expiration applies to Pricing Proposal Version Validity and, where relevant, to whether previously established decision authority remains current for progression or execution. Expiration does not apply to the Pricing Initiative itself and must not erase the historical Approval or Policy Authorisation record.

These conditions must preserve all previous work and activity history.

Revision and Versioning Behaviour

Pricing work is expected to move backward as well as forward.

The lifecycle must therefore support controlled loops such as:

Pricing Proposal Changes Requested → Pricing Initiative returns to In Development or In Review → revised Pricing Proposal version is submitted into the applicable organisational decision path

A material change after a Pricing Proposal has received Approval or Policy Authorisation must not inherit the execution authority attached to the earlier Proposal version.

The materially changed pricing work must create a new controlled Proposal version and complete the applicable organisational decision requirements before receiving execution authority.

Previous Approval or Policy Authorisation records must remain historically attached to the exact Proposal version against which they were made.

Previous Pricing Proposal versions, organisational decisions, Approval records and Policy Authorisation records must never be overwritten.

Urgent Pricing Work

Urgency changes the **speed and priority of the lifecycle**, not the integrity of the lifecycle.

Urgent initiatives can receive:

- priority routing;
- accelerated notifications;

- shorter response windows;
- escalation timers;
- alternate authorised approvers where configured.

Urgency must not automatically remove required governance controls.

Canonical Lifecycle

The canonical Pricing Initiative lifecycle is:

Initiated → In Development → In Review → Awaiting Approval → Ready for Execution → Implemented → Monitoring → Completed

Approval and Policy Authorisation are organisational decision outcomes applied to the relevant Pricing Proposal rather than separate Pricing Initiative lifecycle states.

While the Pricing Initiative is Awaiting Approval, the applicable Pricing Proposal may become:

- Approved;
- Authorised Within Policy;
- Changes Requested;
- Rejected.

Where the Pricing Proposal becomes Approved or validly Authorised Within Policy, and all applicable execution conditions are satisfied, the Pricing Initiative may progress to Ready for Execution.

Where changes are requested, the Pricing Initiative returns to the appropriate In Development or In Review state.

Where a proposal is rejected, the Pricing Initiative may return for further development, remain open for additional analysis, or be cancelled.

2.3 Capability Architecture

CAPABILITY ARCHITECTURE

The MVP consists of interconnected capability systems that together allow pricing work to move through Owómidé from initiation to completion.

The capability architecture below maps directly to the functional areas defined in Sections 3.1 through 3.14.

Each capability has a primary functional owner in Section 3.0.

Capabilities may consume records, rules, evaluations or outputs owned by another functional area where required by the pricing lifecycle, but doing so must not create a second canonical owner or independently redefine the consumed product contract.

1. Organisation Workspace and Access Management

Provides the shared environment in which an organisation's pricing work takes place.

It must support:

- organisation setup;
- users and teams;
- workspace configuration;
- access to active and historical pricing work;
- organisation-level pricing settings and policies.

2. Product and Pricing Context Management

Provides the structured business and pricing context required to perform consequential pricing work.

It must support:

- Priceable Entities, including supported product, SKU or variant, service and other directly priceable offering types;
- categories, product groups and other organisational groupings used to organise or select Priceable Entities;
- pricing dimensions such as location, region, channel, customer group, business unit, vendor and price list;
- Price Records and Current Price;

- Cost Records and Applicable Unit Cost context;
- manual data entry;
- structured CSV import;
- bounded external pricing-context ingestion where supported;
- validation, provenance and freshness of pricing-context information;
- preservation of decision-relevant historical pricing context.

Categories, product groups and pricing dimensions must remain distinguishable from the underlying Priceable Entities.

Current Price must follow the Price Record model defined in Section 3.2 rather than represent an independent pricing object.

Cost-dependent consequential calculations must use the Applicable Unit Cost defined in Section 3.2 rather than an arbitrary Cost Record.

The MVP must provide sufficient business context to perform real pricing work without requiring customers to rebuild their ERP, accounting system or complete operational data environment inside Owómidé.

3. Pricing Initiative Management

Provides the container through which pricing work is created and managed.

It must support:

- creating initiatives;
- defining objectives;
- selecting pricing scope;
- assigning ownership and collaborators;
- tracking initiative status;
- managing urgency and timelines;
- maintaining all related pricing work within one initiative.

4. Collaborative AI Pricing Builder

The Pricing Builder is the core working surface in which users construct the pricing approach associated with a Pricing Initiative.

It must support structured construction of:

- pricing actions;
- pricing strategies and rules;
- parameters;
- assumptions;
- initiative-specific conditions;
- initiative-specific constraints;
- thresholds contained within the pricing logic;
- affected Pricing Scope;
- entity-level exceptions where applicable;
- supported deterministic pricing outputs.

The Builder must be able to reference applicable organisational Guardrails but must not independently create, redefine or own those Guardrails.

Organisational Guardrail definition and configuration remain governed by the Governance capability.

Deterministic calculations and Guardrail evaluations used by the Builder must consume the authoritative outputs of the Pricing Analysis and Scenario Evaluation capability.

The Builder should support both straightforward price changes and more structured pricing approaches without requiring users to write code.

5. Pricing Analysis and Scenario Evaluation

Provides the deterministic analytical environment required to understand the financial and commercial implications of pricing work before formal organisational decision.

It must support, where applicable:

- Current Price or another explicitly identified pricing baseline;
- proposed selling price;
- absolute and percentage price change where validly calculable;
- Applicable Unit Cost and relevant cost basis;
- gross profit;
- gross margin;
- markup;
- deterministic target-margin and target-markup calculations;
- supported promotional, discount and markdown calculations;

- alternative pricing Scenarios;
- Scenario comparison;
- deterministic evaluation of applicable organisational Guardrails;
- calculation traceability;
- preservation of decision-relevant analytical context.

Alternative analytical baselines must remain distinguishable from Current Price.

Guardrail evaluation must consume Governance-defined Guardrails and must not independently create or redefine organisational Guardrails.

The MVP analytical capability is intended to support structured pricing decisions and Scenario evaluation rather than advanced autonomous pricing optimisation.

6. Pricing Proposal Management

Provides the formal decision object through which sufficiently developed pricing work is packaged for organisational decision.

A Pricing Proposal represents the specific pricing action being submitted for decision and remains distinct from the broader Pricing Initiative, exploratory Scenarios and editable Builder work.

It must support:

- creation of a Pricing Proposal from sufficiently developed Initiative work;
- identification of the exact proposed pricing action and affected Pricing Scope;
- Proposal identifiers and controlled versions;
- Proposal readiness;
- a controlled decision snapshot at formal submission;
- Proposal status;
- Proposal version validity;
- distinction between Proposal status and approval progress;
- material-change handling;
- supersession and expiration;
- preservation of historical Proposal versions;
- binding organisational decision and execution authority to the exact controlled Proposal version.

Pricing Proposal Management must not independently perform approval routing, grant approval authority, grant policy authorisation or execute the pricing action.

Those responsibilities remain with Workflow, Governance and Execution.

7. Collaboration and Evidence Management

Allows relevant stakeholders to contribute around the same pricing work while preserving the context to which each contribution relates.

It must support:

- contextual comments;
- mentions;
- assignments;
- supporting evidence and attachments;
- manual market observations where relevant;
- stakeholder contributions;
- review feedback;
- resolution of relevant collaboration items;
- visibility into consequential activity and changes;
- association of collaboration and evidence with the relevant Initiative, Proposal, version or other pricing object.

Collaboration must remain attached to the pricing work it concerns rather than becoming a separate general-purpose messaging system.

Evidence and collaboration must not independently become authoritative pricing data, approval authority or execution authority merely because they are attached to pricing work.

8. Workflow, Review and Approval Management

Controls how Pricing Initiatives and Pricing Proposals progress through required review, organisational decision and execution-readiness processes.

It must support:

- pricing-specific workflow assignment;
- required review requirements within the canonical In Review stage;
- review completion requirements;

- item-level approval where applicable;
- configured policy-authorisation routing where applicable;
- approval routing;
- supported sequential or multiple-approval requirements;
- maker-checker enforcement;
- revision loops;
- Changes Requested treatment;
- rejection treatment;
- bounded urgency, deadline and escalation handling;
- supported approval delegation where organisational policy permits;
- execution-readiness gating;
- workflow visibility and attributable workflow history.

The workflow capability must operate against the exact controlled Pricing Proposal version and must not independently redefine Proposal content, Governance rules, Guardrail calculations or decision snapshots.

Workflow configuration must operate within the canonical Pricing Initiative lifecycle and the bounded configuration model defined in Section 2.4.

The MVP must not allow Workflow configuration to create arbitrary lifecycle states, free-form workflow graphs, user-authored scripts, custom executable expressions, arbitrary triggers or general-purpose automation.

Organisational workflow differences must be represented through supported pricing-specific configuration parameters.

9. Roles, Permissions and Pricing Governance

Controls who may view, create, modify, review, approve, authorise, execute or administer consequential pricing work.

It must support:

- role-based permissions;
- organisational and pricing-scope authority;
- sensitive commercial and cost-data access;
- separation of duties where required;
- approval authority and limits;

- organisational Guardrail definition and configuration;
- Guardrail behavioural treatment;
- policy-authorisation configuration;
- governance enforcement;
- prevention of unauthorised execution;
- attributable governance changes;
- historical governance context.

Governance must be enforced by the system rather than depend solely on documented organisational procedures.

Governance defines applicable organisational controls but must not independently perform deterministic pricing calculations or Guardrail calculations owned by the analytical capability.

10. AI Assistance and AI Governance

AI operates across the workspace as a contextual assistant to authorised users.

AI may assist with activities such as:

- understanding pricing context;
- drafting or refining pricing work;
- translating business intent into structured pricing logic;
- interpreting pricing analysis;
- comparing Scenarios;
- identifying missing or inconsistent information;
- explaining deterministic calculations;
- explaining Guardrail results;
- summarising stakeholder input;
- retrieving relevant historical pricing context;
- preparing pricing work for review;
- summarising recorded post-implementation information.

AI must operate within the invoking user's access and authority.

AI must not independently:

- approve or policy-authorise a Pricing Proposal;
- provide execution authority;
- execute a pricing action;

- become the authoritative deterministic calculation engine;
- become the authoritative Guardrail-evaluation engine;
- bypass organisational permissions or Governance;
- silently apply consequential changes to pricing work.

AI-generated or AI-assisted changes that are applied to pricing work must remain attributable according to the applicable functional requirements.

11. Execution and Post-Implementation Monitoring

Provides continuity between organisational pricing decision authority and the actual operational outcome.

It must support:

- identification of the exact Approved or Authorised Within Policy Pricing Proposal version providing execution authority;
- assignment of implementation responsibility;
- structured execution instructions;
- recording implementation;
- recording the actual implemented pricing state;
- comparison of authorised and implemented pricing;
- identification of execution variance;
- partial implementation and Implementation Exceptions;
- establishment or update of the applicable Current Price where implementation is confirmed and Owómidé maintains the relevant Price Record;
- recording relevant post-implementation results and observations;
- preservation of implementation history and outcome context.

The capability must preserve the distinction between:

Authorised Pricing Action → Actual Implementation → Observed Outcome

Execution must not independently modify or reinterpret the controlled Pricing Proposal version that provides its authority.

12. Versioning, Audit Trail and Pricing Knowledge

Provides persistent organisational memory around pricing.

It must support:

- version history;
- chronological activity history;
- attributable user actions;
- organisational decision history, including Approval and Policy Authorisation records;
- decision rationale;
- execution history;
- historical pricing initiatives;
- search and retrieval of previous pricing work.

Historical records must not be silently overwritten.

13. Notifications, Work Queues and Visibility

Keeps participants aware of relevant pricing work requiring their attention without becoming an independent source of workflow or decision state.

It must support notifications for relevant events such as:

- assignments;
- mentions;
- review requests;
- approval requests;
- requested changes;
- approvals;
- policy authorisations;
- rejections;
- escalations;
- approaching deadlines;
- execution assignments;
- execution-readiness events.

Users should also have role-appropriate work queues and workspace-level visibility into:

- work requiring their attention;
- active Pricing Initiatives;
- review work;
- pending approvals;

- required actions;
- execution responsibilities;
- recently completed work;
- relevant pricing activity.

Notifications, work queues and visibility surfaces must project authoritative underlying product state rather than independently create or redefine that state.

14. Data Export and External Operational Handoff

Provides practical mechanisms for taking supported pricing information and authorised pricing actions from Owómidé into the organisation's external operating environment.

It must support, where applicable:

- structured export of pricing information;
- export of exact authorised Pricing Proposal versions for operational implementation;
- external identifiers required for supported handoff;
- human-readable operational handoff;
- export validation;
- export attribution and auditability;
- bounded integration with selected external systems;
- distinction between export or handoff and confirmed implementation;
- relationship between authorised action, handed-off action and actual implementation.

A supported connector may also exchange inbound pricing-context information where the connector allows it.

Where external information enters Owómidé as pricing context, the semantic ownership of that information remains with Product and Pricing Context Management.

Externally received selling-price information must therefore enter the Price Record model, and externally received cost information must enter the Cost Record model, before being used as authoritative Owómidé pricing context.

The availability of specific native connectors must be driven by validated customer or pilot requirements.

The MVP must not require broad connector coverage, universal bidirectional synchronisation or autonomous publishing into external systems.

Capability Relationship

The core pricing-work flow is:

Product and Pricing Context → Pricing Initiative → Collaborative AI Pricing Builder → Analysis and Scenarios → Collaboration → Pricing Proposal → Review and Organisational Decision Workflow → Execution → Monitoring → Audit and Pricing Knowledge

The Pricing Proposal is the formal decision object between developed pricing work and organisational decision authority.

Organisation Workspace and Access Management, Roles, Permissions and Pricing Governance, AI Assistance and AI Governance, Notifications, Work Queues and Visibility, and Versioning, Audit Trail and Pricing Knowledge operate across the lifecycle rather than as isolated sequential stages.

Governance defines applicable organisational controls.

The analytical capability performs authoritative deterministic calculations and Guardrail evaluations.

Workflow consumes the controlled Proposal and applicable Governance to establish the required organisational decision path.

Execution consumes the exact Proposal version that received valid execution authority.

Data Export and External Operational Handoff bridges authorised Owómidé outputs into supported external operating processes.

Inbound pricing context received through a supported connector must enter the canonical Product and Pricing Context models before being treated as Owómidé pricing context.

Historical records must preserve the exact Proposal, Governance, workflow, execution and pricing context relevant to the decision at the time.

2.4 Scope Boundary

SCOPE BOUNDARY

The MVP must deliver a complete, usable pricing-workflow experience rather than a broad collection of partially implemented pricing capabilities.

A capability belongs in the MVP only when a business must perform real pricing work from initiation through analysis, collaboration, organisational decision, execution recording and monitoring inside Owómidé.

1. In Scope

The MVP includes:

- organisation workspace setup and management;
- user, team, role and permission management;
- Priceable Entity management for supported products, SKUs or variants, services and other directly priceable offerings, plus category and product-group management;
- manual and CSV-based pricing data import;
- bounded external integrations with selected business, spreadsheet, productivity, commerce or operational systems where those integrations materially reduce pricing-workflow friction, with specific connectors prioritised according to validated customer and pilot requirements;
- Price Records and Current Price, Cost Records and Applicable Unit Cost context;
- Pricing Initiative creation and lifecycle management;
- pricing scope selection;
- collaborative AI-native Pricing Builder;
- pricing objectives, strategies, rules, assumptions and parameters, plus Governance-defined organisational Guardrails;
- unit-economics calculations;
- pricing scenario creation and comparison;
- contextual AI assistance;
- comments, mentions, assignments and supporting evidence;
- review and revision behaviour within the canonical Pricing Initiative lifecycle;
- bounded pricing-specific organisational decision routing using supported condition types, Approval rules and Policy Authorisation rules where applicable;
- maker-checker controls, item-level Approval authority and Policy Authorisation governance;

- proposal creation and versioning;
- Approval, Policy Authorisation, Rejection and Changes Requested decision treatment where applicable;
- implementation assignment and recording;
- post-implementation monitoring records;
- activity history and audit trail;
- searchable historical pricing work;
- workspace notifications and work queues;
- structured export of pricing decisions and authorised pricing actions.

2. MVP Configuration Boundary

The MVP must support bounded, pricing-specific configuration without becoming a user-programmable workflow, rules or automation platform.

Organisations should be able to configure supported organisational settings including:

- roles and permissions;
- approval authority and organisational scope;
- organisational Guardrails and supported pricing thresholds;
- relevant pricing dimensions;
- initiative types;
- required fields and participants where supported;
- a bounded Workflow Configuration Profile.

A Workflow Configuration Profile may configure supported workflow parameters such as:

- whether formal review requirements apply within the canonical In Review stage;
- required reviewer roles or participants;
- the applicable organisational decision path;
- required approver roles;
- supported sequential or multiple-approval arrangements;
- approval routing conditions selected from supported pricing-specific condition types;
- target response dates or approval deadlines;
- supported escalation behaviour;
- authorised approval delegation where supported.

Workflow configuration must operate within the canonical Pricing Initiative lifecycle defined in Section 2.2.

Workflow configuration must not:

- create additional Pricing Initiative lifecycle states;
- remove or redefine the meaning of canonical lifecycle states;
- create arbitrary lifecycle transitions outside supported progression and revision behaviour;
- redefine Pricing Proposal statuses or Proposal version-validity states;
- execute user-authored scripts or code;
- evaluate arbitrary executable formulas or expressions as workflow logic;
- create unrestricted user-authored triggers or action chains;
- create arbitrary external actions or automation;
- automate general organisational processes unrelated to pricing;
- bypass Proposal readiness, approval authority, maker-checker controls, Guardrails, policy-authorisation conditions or other Governance requirements.

Different organisational review and decision structures must therefore be represented through supported Workflow Configuration Profile parameters rather than through unrestricted workflow programming.

3. AI Boundary

AI is embedded throughout the workspace but remains assistive.

AI may:

- analyse;
- draft;
- summarise;
- explain;
- compare;
- identify risks;
- retrieve context;
- suggest alternatives;
- assist with calculations and pricing construction.

AI may not independently:

- approve or policy-authorise a Pricing Proposal;
- override permissions, Guardrails or other Governance controls;

- execute consequential pricing actions;
- silently change pricing work that has received Approval or Policy Authorisation, or bypass the applicable Proposal-version and organisational decision requirements.

4. Execution Boundary

The MVP must maintain continuity through execution, but execution does not require Owómidé to automatically publish prices into every operational system.

The MVP must be able to record:

what was proposed → what received organisational decision authority → what was implemented → who implemented it → when it happened → whether implementation differed from the authorised decision baseline.

Manual implementation outside Owómidé remains valid for the MVP.

5. Monitoring Boundary

The MVP supports post-implementation monitoring sufficient to close the pricing lifecycle.

Users can record or import relevant outcomes such as:

- sales;
- volume;
- margin;
- revenue;
- customer or commercial feedback;
- observed pricing outcomes.

The MVP is not required to automatically optimise future prices from these outcomes.

6. Explicitly Out of Scope

The MVP does not include:

- autonomous repricing;
- unattended pricing execution;
- automated continuous competitor-price collection;
- proprietary offline market-data collection infrastructure;
- advanced machine-learning price optimisation;

- automated elasticity modelling;
- autonomous demand forecasting;
- broad, autonomous, or unattended real-time price publishing across ERP, POS, marketplace, and commerce systems;
- broad enterprise connector coverage;
- hardware-based pricing infrastructure;
- general-purpose workflow automation unrelated to pricing;
- arbitrary user-defined Pricing Initiative lifecycle stages or free-form workflow graphs;
- user-authored workflow scripts, custom executable expressions, arbitrary triggers or arbitrary action chains;
- unrestricted user-programmable automation;
- AI acting as an approver or autonomous commercial authority.

These capabilities must not become hidden dependencies for completing the MVP's core pricing workflow.

7. MVP Completeness Test

The MVP scope is complete when a target organisation can:

bring real pricing data into Owómidé → initiate real pricing work → construct and analyse the pricing approach → collaborate → review and revise → apply organisational controls → complete the applicable organisational decision path → establish execution authority → record implementation → monitor the result → retrieve the complete decision history

without requiring any out-of-scope capability for that workflow to succeed.

3. Functional Requirements

3
FUNCTIONAL REQUIREMENTS

3.1. Organisation Workspace and Access Management

3.2. Product and Pricing Context Management

3.3. Pricing Initiative Management

3.4. Collaborative AI Pricing Builder

3.5. Pricing Analysis and Scenario Evaluation

3.6. Pricing Proposal Management

3.7. Collaboration and Evidence Management

3.8. Workflow, Review and Approval Management

3.9. Roles, Permissions and Pricing Governance

3.10. AI Assistance and AI Governance

3.11. Execution and Post-Implementation Monitoring

3.12. Versioning, Audit Trail and Pricing Knowledge

3.13. Notifications, Work Queues and Visibility

3.14. Data Export and External Operational Handoff

Requirement Interpretation and Criticality

REQUIREMENT INTERPRETATION AND CRITICALITY

This section defines how requirement language must be interpreted throughout Section 3.

Requirement Strength

Term	Meaning	MVP Effect
Must / Must Not	Mandatory functional behaviour or constraint.	Required for MVP wherever the stated condition applies.
Should / Should Not	Expected MVP behaviour that improves completeness or usability.	May be deferred only through an explicit product decision and only where the deferral does not break a mandatory requirement, canonical product model, core pricing workflow, governance integrity, historical integrity or supported non-AI workflow.
May	Permitted or optional behaviour.	Does not by itself create a mandatory MVP requirement.
Not Required / Does Not Require	Explicitly outside the minimum MVP obligation.	Does not need to be delivered unless introduced through a separate explicit scope decision.

Conditional Language

Where applicable / Where relevant

The requirement applies only when the stated condition exists.

Where that condition applies, any associated **Must** or **Must Not** requirement remains mandatory.

At minimum

Every listed item is mandatory.

Additional supported items may also be provided.

Examples

Terms such as:

- **such as**
- **for example**
- **may include**

introduce illustrative examples unless the surrounding requirement explicitly makes the listed examples mandatory.

Examples must not silently expand the MVP scope.

Canonical Requirement References

Where one requirement references another canonical requirement, the referenced requirement remains authoritative for the underlying product contract. A consuming requirement must not redefine, weaken or create a competing version of that contract.

Interpretation Principle

Requirement strength must be determined by the language of the requirement, not by:

- feature prominence;
- interface placement;
- section length;
- implementation convenience;
- frequency of mention elsewhere in the PRD.

A possible product behaviour must not be interpreted as mandatory merely because it is described in the PRD.

Mandatory MVP functional acceptance must ultimately be traceable to:

- an explicit **Must** or **Must Not** requirement; or
- another mandatory requirement that makes the behaviour necessary.

3.1 Organisation Workspace and Access Management

1. ORGANISATION WORKSPACE AND ACCESS MANAGEMENT

The Organisation Workspace is the controlled environment in which a customer manages its users, configuration, pricing data, and pricing work.

1.1. ORG-001 Organisation Workspace Creation

An authorised organisation administrator must be able to create and configure an organisation workspace.

The workspace must capture at minimum:

- organisation name;
- industry or sector;
- primary operating country;
- operating markets where relevant;
- default currency;
- time zone.

These settings must be editable by authorised administrators.

1.2. ORG-002 Workspace Data Isolation

Each organisation's:

- users;
- pricing data;
- initiatives;
- proposals;
- analysis;
- comments;
- Approval records and Policy Authorisation records;
- execution records;
- configuration;
- history

must remain isolated from other organisations.

A user must never gain access to another organisation's information without explicit authorised membership.

1.3. ORG-003 User Invitation

Authorised administrators must be able to invite users into the workspace.

An invitation must include:

- email address;
- assigned role or roles;
- applicable access scope where required.

Invitation states must include:

- Pending
- Accepted
- Expired
- Revoked

1.4. ORG-004 User Membership States

A workspace member must have a defined membership state:

- Active
- Suspended
- Deactivated

Suspended or deactivated users must immediately lose protected workspace access.

Previous activity, comments, Pricing Proposals, Approval records, Policy Authorisation records and other historical actions associated with that user must remain preserved.

1.5. ORG-005 Roles and Access Assignment

Authorised administrators must be able to assign and modify user roles.

A user may hold more than one role where required by the organisation.

Role assignment must not automatically remove identity-level governance restrictions such as maker-checker controls.

Detailed role and permission behaviour is defined separately in the governance requirements.

1.6. ORG-006 Scope-Based Access

Where relevant, access must be capable of being limited to organisational scope such as:

- category;
- product group;
- region;
- location;
- channel;
- business unit;
- vendor or marketplace scope.

A user's effective access must be determined by both their assigned role and applicable scope.

1.7. ORG-007 Sensitive Information Access

Authorised administrators must be able to control access to sensitive pricing information, including cost-related information.

Users without permission to access cost information must not receive that information through:

- workspace screens;
- exports;
- AI responses;
- calculations from which restricted information can be directly derived.

1.8. ORG-008 Workspace Administration

Authorised administrators must be able to manage:

- organisation profile;
- members;
- roles;
- access scopes;
- workspace configuration;

- pricing policies;
- guardrails;
- workflow configuration.

Administrative authority must remain separate from commercial pricing authority unless the same user has explicitly been granted both.

1.9. ORG-009 Account Ownership

Each organisation must have at least one designated Account Owner responsible for top-level workspace administration.

The system must prevent removal or deactivation of the final Account Owner until ownership has been transferred or another Account Owner has been assigned.

Account ownership alone must not automatically grant authority to approve or execute pricing decisions.

1.10. ORG-010 Authentication and Session Access

Users must authenticate before accessing protected workspace information.

The MVP must support:

- secure sign-in;
- sign-out;
- password recovery or equivalent account recovery;
- session expiration;
- invalid-session handling;
- access revocation following suspension or deactivation.

Enterprise SSO is not required for the initial MVP unless validated as a contractual requirement for a target customer.

1.11. ORG-011 Organisation Setup Progress

The workspace must provide a clear setup path allowing an organisation to become operational by completing the minimum requirements for real pricing work.

This includes:

1. organisation configuration;
2. user and role setup;
3. product and pricing data setup;
4. basic pricing guardrail configuration;
5. workflow and organisational decision configuration, including item-level approval and policy authorisation where applicable;
6. creation of the first Pricing Initiative.

Setup must not require completion of non-essential configuration before the organisation can begin using the product.

1.12. ORG-012 Administrative Auditability

Consequential workspace administration actions must be recorded in the audit history.

This includes:

- user invitations;
- activation and deactivation;
- role changes;
- scope changes;
- sensitive-data access changes;
- ownership changes;
- pricing-policy changes;
- workflow configuration changes;
- guardrail changes.

Each record must identify:

- action;
- actor;
- timestamp;
- previous state where relevant;
- resulting state.

1.13. ORG-013 Deletion and Historical Integrity

Removing a user or changing organisational configuration must not destroy historical pricing records.

Past Pricing Initiatives, Approval records, Policy Authorisation records, comments and other consequential actions must continue to display the identity and authority context that existed when those actions occurred.

1.14. ORG-014 Minimum Workspace Readiness

An organisation is ready to begin real pricing work when it has:

- an active organisation workspace;
- at least one authorised workspace administrator;
- at least one active pricing user;
- sufficient product or pricing context to create an initiative;
- applicable pricing controls configured where required;
- an available workflow for progressing the initiative.

Workspace readiness is distinct from MVP activation. Activation occurs only when the organisation completes its first real structured pricing workflow.

3.2 Product and Pricing Context Management

2. PRODUCT AND PRICING CONTEXT MANAGEMENT

The MVP must provide enough structured business context for users to perform real pricing work without requiring Owómidé to become the organisation's ERP or system of record.

2.1. DATA-001 Priceable Entity

The workspace must support the creation and management of Priceable Entities.

A Priceable Entity is a business offering to which the organisation can assign or evaluate a distinct selling price within an applicable pricing context.

Supported Priceable Entity types must include, at minimum:

- product;
- SKU or product variant;
- service;
- another organisation-defined directly priceable offering.

A product may itself be a Priceable Entity where the organisation prices that product directly.

Where individual SKUs or variants of a product have distinct selling prices, each independently priced SKU or variant must be represented as its own Priceable Entity.

Categories and product groups must not become Priceable Entities solely because they are used to organise, filter or apply pricing work across multiple Priceable Entities.

Pricing dimensions such as location, region, channel, customer group, business unit, vendor or price list must remain distinct from the Priceable Entity itself.

A Priceable Entity may therefore have different Price Records, Cost Records or pricing outcomes across supported pricing dimensions without becoming a different Priceable Entity unless the organisation's underlying commercial object is itself different.

Each Priceable Entity must have, at minimum:

- unique Owómidé identifier;
- organisation-defined name;
- entity type;

- status.

Where available, a Priceable Entity may also contain:

- SKU, product code or external identifier;
- parent product or related organisational grouping;
- category;
- brand;
- base unit of measure;
- description;
- organisation-specific reference fields.

Currency must be associated with the applicable monetary record or pricing context rather than assumed to be an immutable property of the Priceable Entity.

The Priceable Entity model must remain sufficiently flexible to support organisations that price at product, SKU, variant or service level without requiring every organisation to use the same catalogue hierarchy.

2.2. DATA-002 Organisation Pricing Dimensions

The organisation must be able to structure pricing context using relevant dimensions such as:

- location;
- region;
- channel;
- customer group;
- business unit;
- vendor;
- price list.

Dimensions must be reusable across Pricing Initiatives rather than manually recreated for every workflow.

2.3. DATA-003 Price Record and Current Price

The system must allow an organisation to maintain structured Price Records for Priceable Entities.

A Price Record represents a selling-price value for a Priceable Entity within a defined pricing context.

Each Price Record must identify, where applicable:

- Priceable Entity;
- price amount;
- currency;
- applicable pricing dimensions;
- effective-from date or timestamp;
- effective-to date or timestamp where applicable;
- source;
- last updated timestamp.

The system must support different Price Records for the same Priceable Entity where pricing legitimately differs by location, channel, customer group, price list, currency or another configured pricing dimension.

The system must also preserve multiple Price Records over time for the same pricing context where the selling price changes.

Current Price means the specific Price Record that is presently applicable to a Priceable Entity within the relevant pricing context at the applicable reference time.

A Current Price must therefore remain associated with:

- the Priceable Entity;
- price amount;
- currency;
- applicable pricing dimensions;
- effective context;
- source Price Record.

The system must not silently treat the newest Price Record, most recently imported value or another arbitrary Price Record as the Current Price where more than one record could apply.

For the same Priceable Entity and exact pricing context, the system must not represent conflicting Price Records as simultaneously being the Current Price for the same reference time.

Where overlapping, conflicting or insufficiently specified Price Records prevent the Current Price from being determined unambiguously, the system must identify the Current Price as unresolved and require appropriate authorised correction or selection rather than silently choosing a value.

A future-effective Price Record must not become Current Price before its applicable effective time.

A historical Price Record must remain preserved after it ceases to be Current Price.

Where no applicable Price Record exists, Current Price must be represented as unavailable rather than assumed to be zero or inferred from another pricing context.

Any consequential pricing work that uses Current Price must remain traceable to the exact Price Record and pricing context from which that Current Price was determined.

2.4. DATA-004 Cost Record and Applicable Unit Cost

Where cost information is available, the MVP must allow authorised users to maintain structured Cost Records for priceable entities.

A Cost Record represents an organisation-supplied or externally sourced cost value. It must not be assumed to represent a universal accounting definition of cost.

Each Cost Record must identify, where applicable:

- affected priceable entity;
- cost amount;
- currency;
- unit of measure or cost unit;
- cost basis;
- applicable pricing dimensions;
- effective date or effective period;
- source;
- last updated timestamp.

Cost basis must identify what the cost value represents. Supported cost bases may include:

- acquisition or purchase cost;
- landed cost;

- production or manufacturing cost;
- direct service-delivery cost;
- another organisation-defined cost basis.

The MVP must allow more than one Cost Record to exist for the same priceable entity where the records represent different cost bases, pricing dimensions or effective periods.

Owómidé must not silently treat the newest Cost Record, an average historical cost or any particular cost basis as the correct cost for every pricing decision.

For every deterministic pricing calculation that requires cost, the system must identify the Applicable Unit Cost used by that calculation.

Applicable Unit Cost means the specific cost value and cost basis selected for the relevant pricing context and expressed on a unit basis compatible with the selling price being analysed.

The Applicable Unit Cost must be traceable to either:

- a structured Cost Record; or
- an explicit assumed cost permitted under the applicable assumption requirements.

The calculation context must preserve enough information to identify:

- cost amount used;
- cost basis used;
- currency;
- applicable unit of measure;
- applicable pricing dimensions;
- source Cost Record or explicit assumption;
- effective context relevant to the pricing decision.

Where multiple potentially applicable Cost Records exist and the correct cost basis cannot be determined from the pricing context or organisation configuration, the system must require an authorised user to identify the applicable cost rather than selecting one silently.

Where a cost cannot be expressed on a unit basis compatible with the selling price, the system must not use that value directly in gross-profit, gross-margin, markup or target-price calculations.

The MVP is not required to operate as a full cost-accounting system, perform enterprise-wide overhead allocation or independently construct accounting cost values from incomplete source data.

Changes to cost information over time must create or preserve historical cost context rather than overwriting the cost basis used in earlier consequential pricing work.

2.5. DATA-005 Historical Price and Cost Context

Owómidé must preserve previous Price Records and Cost Records required to understand historical pricing decisions.

Establishing a new Current Price must not overwrite the Price Record that represented the previous Current Price.

The previous Price Record must remain historically identifiable with its original:

- price amount;
- currency;
- applicable pricing dimensions;
- effective context;
- source;
- available provenance.

Changes to Cost Records must follow the historical-integrity requirements defined in DATA-004.

Updating current workspace pricing or cost context must not destroy or reinterpret the values used in an earlier Pricing Initiative or submitted Pricing Proposal.

Historical pricing work must continue to resolve to the exact decision-relevant pricing context preserved for that work rather than to later workspace values.

2.6. DATA-006 Manual Data Entry

Authorised users must be able to create and update supported pricing-context records manually.

Manual entry must apply the same:

- validation;

- permissions;
- audit;
- provenance;
- historical-integrity

requirements as imported or externally supplied pricing data.

Where a user manually enters selling-price information, that information must enter Owómidé through the Price Record model defined in DATA-003.

A manually entered price may become the Current Price only where the applicable Priceable Entity, pricing dimensions, currency and effective context are sufficiently identified and the Current Price can be determined without unresolved conflict.

A manual selling-price change that establishes a new Current Price must preserve the previous Price Record in accordance with DATA-005 rather than overwrite the historical price value.

Where manual entry creates overlapping, conflicting or insufficiently specified Price Records that prevent Current Price from being determined unambiguously, the system must identify the Current Price as unresolved rather than silently selecting a record.

Manual entry of cost information must continue to follow the Cost Record and Applicable Unit Cost requirements defined in DATA-004.

2.7. DATA-007 CSV Import

The MVP must support structured CSV import for product and pricing data.

At minimum, users should be able to import:

- product or SKU identifiers;
- product names;
- categories;
- Price Records, including price amount and, where available, currency, applicable pricing dimensions and effective context;
- cost records where authorised, including cost amount and cost basis and, where available, currency, unit or cost unit, applicable pricing dimensions and effective date;
- currencies;
- supported pricing dimensions.

Imported selling-price information must enter Owómidé through the Price Record model defined in DATA-003.

Where imported information identifies a price as currently applicable, that price may become the Current Price only where the affected Priceable Entity, pricing context and effective applicability can be determined without unresolved conflict.

An imported price value must not silently replace the existing Current Price merely because it is the newest imported record.

CSV import must remain available as a supported ingestion mechanism where a direct external-system integration is unavailable, unsupported or unnecessary.

2.8. DATA-008 Import Mapping

Users must be able to map incoming CSV columns to Owómidé fields before committing an import.

The system should identify:

- recognised fields;
- unmapped fields;
- required fields that are missing;
- invalid values;
- duplicate identifiers;
- rows that cannot be imported.

The user must be able to review validation results before committing the import.

2.9. DATA-009 Import Error Handling

A failed row must not silently corrupt or invalidate successfully structured pricing data.

The import process must provide:

- row-level error visibility;
- reason for rejection;
- affected field;
- ability to correct and retry.

The system must clearly distinguish successfully imported, skipped and failed records.

2.10. DATA-010 Duplicate Handling

Owómidé must prevent accidental creation of duplicate priceable entities where a reliable organisation identifier already exists.

Where an imported identifier matches an existing entity, the user must be able to determine whether the operation should:

- update the existing record;
- skip the incoming record;
- resolve the conflict before import.

2.11. DATA-011 Data Source and Provenance

Pricing-context data used in a decision should retain its available source information.

The source may be:

- manual entry;
- CSV import;
- supported external integration;
- user-provided evidence;
- another supported MVP input mechanism.

Where known, the system should preserve the originating system or source, the user or integration responsible for introducing the information, and the relevant import, retrieval or synchronisation timestamp.

Where structured Pricing Context is created from user-provided Evidence, the Evidence may be retained as source provenance, but the Evidence itself must not automatically become authoritative Pricing Context.

A selling-price value originating from Evidence must enter the Price Record model and satisfy the applicable DATA-003 requirements before it can be treated as Current Price.

A cost value originating from Evidence must enter the Cost Record model and satisfy the applicable DATA-004 requirements before it can be used as an authoritative structured Cost Record or selected as the Applicable Unit Cost.

Evidence provenance must remain distinguishable from the structured Pricing Context record created from that Evidence.

2.12. DATA-012 Data Freshness

Pricing records must display when they were last updated.

Where an initiative uses potentially stale information, the age of the relevant data must remain visible to the user.

The MVP should not represent manually supplied or previously imported information as real-time data.

2.13. DATA-013 Pricing Context Snapshot

When a Pricing Proposal is formally submitted into an organisational decision path, the material pricing context used to construct and analyse that Proposal version must be preserved as part of its controlled decision basis.

Where applicable, the preserved pricing context must include:

- the exact Current Price or other Price Record materially used as the pricing baseline, including the source Price Record, applicable pricing dimensions and relevant effective context;
- Applicable Unit Cost used in decision-relevant calculations;
- cost basis associated with that Applicable Unit Cost;
- currency;
- applicable unit of measure;
- source Cost Record or explicit cost assumption;
- applicable pricing dimensions;
- other structured pricing-context values materially used in the analysis;
- relevant source and freshness information.

Where Current Price formed part of the submitted Proposal's decision basis, the snapshot must preserve the exact Price Record that represented Current Price for that pricing context rather than retaining only an untraceable numeric price value.

Where an explicit assumed cost is used instead of a structured Cost Record, the snapshot must preserve that the value was assumed and must not represent it as verified organisational cost data.

Subsequent changes to Cost Records, prices or other underlying workspace information must not silently modify, recalculate or reinterpret the pricing context preserved with the submitted Proposal version.

Historical pricing work must therefore remain understandable using the exact decision-relevant context that applied at the time rather than current workspace values.

2.14. DATA-014 Pricing Scope Selection

When creating or developing a Pricing Initiative, authorised users must be able to define the Pricing Scope affected by the work.

Pricing Scope must identify one or more Priceable Entities.

Users may establish the affected Priceable Entity set through:

- direct selection of Priceable Entities;
- supported category or product-group selection;
- another supported organisational grouping that resolves to Priceable Entities.

Users must also be able to apply relevant pricing dimensions such as:

- location;
- region;
- channel;
- customer group;
- business unit;
- vendor;
- price list;
- other configured pricing dimensions.

A category, product group or pricing dimension used for scope selection must remain distinguishable from the Priceable Entities included through that selection.

The system must allow users to understand both:

- how the scope was selected; and
- which Priceable Entities and pricing-dimension combinations are currently included.

Before a Pricing Proposal is formally submitted, the affected scope must resolve to an explicit set of Priceable Entities and applicable pricing dimensions.

The system must not submit a Proposal whose affected commercial scope cannot be determined.

2.15. DATA-015 Bulk Pricing Scope

The MVP must support Pricing Initiatives affecting more than one Priceable Entity.

Multiple Priceable Entities may enter the same Pricing Scope through direct selection or through a supported grouping selector such as a category or product group.

A grouping selector must not require the user to manually add every qualifying Priceable Entity individually where the system can resolve the group membership.

Users must be able to apply common pricing work across the resulting Priceable Entity set while preserving the ability to identify entity-level results, exceptions and missing information.

The product must not require a separate Pricing Initiative for every SKU or other Priceable Entity where the affected entities form part of the same logical pricing action.

2.16. DATA-016 Data Validation

The system must validate structured pricing data before it is used in calculations or submitted as part of formal pricing work.

Validation should detect relevant issues including:

- missing required values;
- invalid numeric formats;
- unsupported currencies;
- negative values where not permitted;
- inconsistent pricing scope;
- duplicate records;
- overlapping or conflicting Price Records that could represent more than one Current Price for the same Priceable Entity, exact pricing context and reference time;
- Price Records whose pricing dimensions or effective context are insufficient to determine their applicability where Current Price is required;
- invalid effective dates.
- cost information that is missing or incompatible with the cost basis, currency, unit or pricing context required for its intended calculation use.

Invalid data must be clearly identified rather than silently corrected by the system.

Where Price Record validation identifies ambiguity that prevents a unique Current Price from being determined under DATA-003, the affected Current Price must remain unresolved until the ambiguity is appropriately corrected or resolved.

A Price Record may remain preserved as historical or contextual information where appropriate, but the system must not use an ambiguous Price Record as Current Price for consequential pricing work.

A Cost Record may remain usable as pricing context where optional information is unavailable, but it must not be used as the Applicable Unit Cost for a deterministic calculation unless the requirements in DATA-004 for that calculation are satisfied.

2.17. DATA-017 Restricted Pricing Context

Cost and other restricted commercial information must respect the user's access permissions.

Restricted values must not be exposed through:

- direct fields;
- initiative context;
- exports;
- AI responses;
- derived calculations that would reveal the restricted value.

2.18. DATA-018 Archiving

Authorised users must be able to archive priceable entities that are no longer actively priced.

Archiving must not remove those entities from historical Pricing Initiatives, Pricing Proposals, Approval records, Policy Authorisation records or Execution Records.

2.19. DATA-019 Pricing Context Search and Filtering

Users must be able to locate relevant priceable entities using available identifiers and dimensions.

The MVP should support filtering by relevant attributes such as:

- name;
- SKU or identifier;
- category;
- status;
- location;
- channel.

2.20. DATA-020 Minimum Context Requirement

A Pricing Initiative must not require every possible business-data field before work can begin.

Owómidé must allow users to begin with the information available while clearly identifying missing information that becomes necessary for a calculation, Guardrail evaluation, review or organisational decision.

The system must distinguish between:

- optional context;
- required workflow information;
- required calculation inputs;
- required organisational decision inputs.

This allows organisations with imperfect or fragmented data to use the MVP without weakening the integrity of consequential pricing decisions.

2.21. DATA-021 Bounded External Data Integration

The MVP must support a bounded external data-integration capability for selected business or productivity systems where direct connectivity materially reduces the effort required to establish or maintain pricing context.

Supported integrations may provide access to relevant information such as:

- priceable entities and external identifiers;
- product or service attributes;
- Price Records, including current-known prices where supplied;
- cost information where authorised, including the available cost amount, cost basis, currency, unit or cost unit, applicable pricing dimensions and effective context;
- categories and other pricing dimensions;

- other supported pricing-context fields.

Where an external integration supplies cost information, that information must enter Owómidé through the Cost Record model defined in DATA-004.

Where an external integration supplies selling-price information, that information must enter Owómidé through the Price Record model defined in DATA-003.

An externally supplied value described as a current price may become the Current Price only where its Priceable Entity, pricing dimensions, currency and effective applicability are sufficiently identified and no unresolved conflicting Price Record prevents a unique determination.

Receipt of a newer external price value must not by itself cause Owómidé to silently replace the existing Current Price.

An externally supplied cost value must not automatically become the Applicable Unit Cost solely because it was received from an integrated system.

Selection or determination of the Applicable Unit Cost for consequential pricing calculations must continue to follow DATA-004, including applicable cost-basis, unit, currency, pricing-dimension and ambiguity requirements.

At least one external connector should be supported as part of the MVP, with the specific system selected according to validated customer or pilot requirements.

Additional connectors must not automatically become MVP requirements.

Data received through an external integration must:

- pass applicable Owómidé validation rules;
- preserve its originating source;
- preserve the relevant retrieval or synchronisation timestamp;
- respect workspace permissions and sensitive-data controls;
- distinguish externally sourced information from manually entered information;
- avoid being represented as real-time where the integration does not provide real-time data.

Failure or unavailability of an external integration must not corrupt existing pricing records or prevent use of supported manual or structured-import alternatives.

The MVP does not require universal bidirectional synchronisation with external business systems.

3.3 Pricing Initiative Management

3. PRICING INITIATIVE MANAGEMENT

The Pricing Initiative is the primary container for real pricing work in the MVP.

It must hold the business objective, Pricing Scope, working context, analysis, collaboration, Pricing Proposals, workflow state, organisational decision records including Approval and Policy Authorisation records, Execution Records and history associated with a defined piece of pricing work.

3.1. INIT-001 Create Pricing Initiative

An authorised user must be able to create a Pricing Initiative.

At minimum, creation must capture:

- initiative title;
- objective or reason;
- initiative type;
- owner;
- pricing scope;
- priority or urgency.

Additional context may be added during development rather than being required at creation.

3.2. INIT-002 Initiative Types

The MVP must support common pricing-work types including:

- price increase;
- price decrease;
- scheduled price review;
- cost-driven repricing;
- margin protection;
- competitor-response pricing;
- promotion or campaign pricing;
- new product or service pricing;
- inventory markdown or clearance;
- category or portfolio review;

- pricing strategy or rule change;
- other organisation-defined pricing work.

Initiative type should provide structure without forcing every initiative into a rigid workflow.

3.3. INIT-003 Pricing Objective

Every Pricing Initiative must contain a clearly defined pricing objective.

The objective should explain what the organisation is attempting to achieve, such as:

- protect margin;
- improve profitability;
- increase revenue;
- improve competitiveness;
- support volume growth;
- respond to cost changes;
- clear inventory;
- support market entry;
- execute a promotion;
- establish pricing for a new offering.

Users must also be able to provide a free-text objective where predefined categories are insufficient.

3.4. INIT-004 Initiative Scope

Every Pricing Initiative must identify the Pricing Scope affected by the work.

The Initiative Scope must follow the Pricing Scope model defined in DATA-014.

The scope must identify:

- the affected Priceable Entities;
- the applicable pricing dimensions;
- any category, product group or other grouping selector used to establish the affected Priceable Entity set.

A category, product group, location, channel, customer group, price list or other pricing dimension must not be treated as a Priceable Entity solely because it forms part of the Initiative Scope.

Where a grouping selector is used, users must be able to determine which Priceable Entities are currently included by that selector.

Scope changes during development must remain visible and must be recorded where consequential.

Before formal Proposal submission, the scope must be sufficiently resolved to identify the exact Priceable Entities and applicable pricing dimensions affected by the proposed pricing action.

3.5. INIT-005 Initiative Ownership

Every active Pricing Initiative must have one accountable owner.

The owner is responsible for coordinating progression of the initiative but does not automatically receive authority to approve or execute it.

Ownership may be transferred by an authorised user.

Ownership changes must be recorded.

3.6. INIT-006 Collaborators

Authorised users must be able to add relevant participants to an initiative.

Participants may contribute according to their permissions through activities such as:

- analysis;
- comments;
- supporting information;
- review;
- approval;
- implementation;
- monitoring.

Participation in an initiative must not override the user's organisation-level permissions.

3.7. INIT-007 Initiative Summary

Every Pricing Initiative must provide a persistent summary containing at minimum:

- title;
- objective;
- initiative type;
- owner;
- pricing scope;
- lifecycle status;
- urgency;
- current proposal state where applicable;
- responsible next participant or action where applicable.

This summary must remain understandable without requiring the user to reconstruct the initiative from its activity history.

3.8. INIT-008 Lifecycle State

A Pricing Initiative must support the following primary lifecycle states:

- Initiated;
- In Development;
- In Review;
- Awaiting Approval;
- Ready for Execution;
- Implemented;
- Monitoring;
- Completed;
- Cancelled.

These states represent the overall progression of the Pricing Initiative.

Proposal-specific decision states such as Approved, Rejected, Changes Requested, or Authorised Within Policy must not be represented as Pricing Initiative lifecycle states.

The system must clearly display the current Pricing Initiative lifecycle state to authorised users.

3.9. INIT-009 Controlled State Transitions

Pricing Initiative state transitions must follow defined product and workflow rules.

A Pricing Initiative must not progress to a later lifecycle state where required conditions for that transition remain unresolved.

In particular:

- an initiative must not enter In Review where required development information is incomplete;
- an initiative must not enter Awaiting Approval until applicable review and proposal-readiness requirements are satisfied;
- an initiative must not enter Ready for Execution unless the current applicable Pricing Proposal is Approved or validly Authorised Within Policy and all applicable execution conditions are satisfied;
- an initiative must not enter Implemented until implementation has been appropriately recorded or confirmed;
- an initiative must not enter Completed until applicable completion conditions are satisfied.

Where changes are requested or material revisions are required, the Pricing Initiative must return to the appropriate earlier lifecycle state.

State transitions must remain attributable and auditable.

3.10. INIT-010 Initiative Priority and Urgency

Users must be able to indicate the priority or urgency of pricing work.

The MVP should support a bounded priority model such as:

- Normal;
- High;
- Urgent.

Priority may influence:

- work ordering;
- notifications;

- escalation;
- response expectations.

Urgency must not bypass governance requirements.

3.11. INIT-011 Target and Effective Dates

Where relevant, an initiative must support dates including:

- target decision date;
- proposed effective date;
- expiry date where applicable.

Dates must remain visible to relevant participants throughout the workflow.

Changes to consequential dates must be recorded.

3.12. INIT-012 Initiative Context Aggregation

The Pricing Initiative must provide a coherent view of the decision-relevant information associated with the pricing work without creating a separate competing information type called Initiative Context.

The Initiative may surface or reference, according to the user's permissions:

- structured Product and Pricing Context governed by Section 3.2;
- supporting Evidence governed by Section 3.7;
- explicit Assumptions governed by INIT-013, BUILD-008 and ANALYSIS-017;
- the pricing objective and business rationale;
- relevant Pricing Builder work;
- analysis and Scenarios;
- Pricing Proposals;
- collaboration and review activity;
- workflow and organisational decision information;
- execution and monitoring information where applicable.

Information surfaced through the Initiative must retain its originating product object, information type, source, provenance and relevant version context.

Displaying information within a Pricing Initiative must not:

- convert supporting Evidence into authoritative structured Pricing Context;
- convert an Assumption into verified organisational data;
- convert a comment or discussion into Evidence merely because it is visible within the Initiative;
- create a second copy of a structured Price Record, Cost Record or other canonical Pricing Context record.

Supporting documents, observations, market information, stakeholder feedback and similar supporting material must be managed as Evidence under Section 3.7 where they are intended to support or challenge pricing work.

Structured pricing information intended to operate as authoritative Owómidé Pricing Context must follow the applicable requirements in Section 3.2.

The Pricing Initiative therefore acts as the organising container and contextual view across these information classes rather than becoming a separate canonical owner of them.

3.13. INIT-013 Initiative-Level Assumptions

Users must be able to record explicit Assumptions that materially influence pricing work.

An Assumption is an explicitly identified premise, estimate or working value relied upon where:

- verified information is unavailable;
- an alternative condition is deliberately being tested;
- a Scenario requires a hypothetical input; or
- organisational judgement is intentionally being used instead of verified structured information.

An Assumption must remain distinguishable from:

- structured Pricing Context governed by Section 3.2;
- supporting Evidence governed by Section 3.7;
- verified organisational data;
- AI inference;
- comments or stakeholder discussion;
- pricing parameters or commercial targets that are known rather than assumed.

Where applicable, a material Assumption should identify:

- the assumed value, condition or premise;
- the user responsible for introducing it;
- the pricing work, Scenario, calculation or Pricing Scope to which it applies;
- the reason or basis for the Assumption;
- supporting Evidence where available;
- creation or application timestamp;
- relevant version context.

Evidence may support an Assumption without converting that Assumption into verified organisational data.

Where verified information later replaces an Assumption in current pricing work, historical controlled versions must continue to preserve the Assumption that formed part of their original decision basis.

Important Assumptions must not exist solely inside comments, attachments or AI conversations.

Material Assumptions relied upon by a submitted Pricing Proposal must remain preserved with the applicable controlled Proposal version in accordance with PROP-011.

3.14. INIT-014 Initiative Readiness

Before an initiative can progress into formal review, the system must determine whether required initiative information is present.

Readiness checks may include:

- objective defined;
- affected scope identified;
- required pricing inputs available;
- analysis completed where required;
- applicable guardrails evaluated;
- proposed action sufficiently defined.

Missing requirements must be identified to the user.

3.15. INIT-015 Initiative Duplication

An authorised user should be able to create a new Pricing Initiative based on an existing initiative where the previous structure is relevant.

The new initiative may reuse permitted elements such as:

- scope;
- objective structure;
- strategy or rules;
- assumptions;
- workflow configuration.

Historical organisational decision records, including Approval and Policy Authorisation records, and historical Execution Records must not be copied or transferred as valid authority for the new Pricing Initiative.

3.16. INIT-016 Initiative Search and Filtering

Users must be able to locate Pricing Initiatives using relevant criteria such as:

- title;
- owner;
- status;
- initiative type;
- urgency;
- product or category;
- location or channel;
- creation date;
- effective date.

Search results must respect the user's access scope.

3.17. INIT-017 Personal Work Visibility

Users must be able to identify initiatives requiring their attention.

This includes work where the user is:

- owner;
- collaborator;
- reviewer;

- approver;
- implementation owner;
- mentioned or assigned an action.

This requirement supports a task-oriented workspace rather than forcing users to manually inspect every active initiative.

3.18. INIT-018 Hold and Cancel

Authorised users must be able to place a Pricing Initiative On Hold or Cancel it.

The system must record:

- action;
- actor;
- timestamp;
- reason.

On Hold must temporarily pause progression without deleting or resetting the initiative's existing lifecycle context.

Cancelled initiatives must retain their existing pricing work and history.

Neither condition may delete the underlying pricing record.

Expiration of a Pricing Proposal version or loss of current execution authority must be handled through the applicable Proposal-validity, workflow and governance requirements rather than through the Pricing Initiative lifecycle.

3.19. INIT-019 Initiative Completion

An initiative may be completed only when its applicable pricing workflow has reached a resolved end state.

Completion should capture:

- final decision;
- execution status;
- relevant outcome or monitoring information where applicable;

- completion date.

Completed initiatives become read-only for consequential historical records, except for permitted monitoring information, annotations or administrative corrections that remain separately auditable.

3.20. INIT-020 Initiative Historical Integrity

The Pricing Initiative must remain the persistent record of the pricing work.

The system must preserve the relationship between:

objective → context → analysis → pricing logic → Pricing Proposal → review → organisational decision authority → implementation → outcome

Users reviewing a completed initiative must be able to understand how the final pricing action was reached without reconstructing the process from external communication.

3.21. INIT-021 Initiative and Proposal Separation

A Pricing Initiative and a Pricing Proposal must remain separate product objects.

The initiative represents the complete body of pricing work.

A proposal represents a specific action submitted for decision.

An initiative may therefore contain:

- exploratory analysis without a submitted proposal;
- multiple scenarios;
- multiple proposal versions;
- a rejected proposal followed by a revised proposal;
- historical proposals that are no longer current.

Only the Current Pricing Proposal version, while valid for progression, may proceed through the active organisational decision and execution path.

3.4 Collaborative AI Pricing Builder

4. COLLABORATIVE AI PRICING BUILDER

The Collaborative AI Pricing Builder is the core working environment in which users construct the pricing approach associated with a Pricing Initiative.

The builder must translate pricing intent into structured, reviewable and executable pricing logic without requiring users to write code or work across disconnected spreadsheets and documents.

It must support both straightforward price changes and more structured pricing strategies while preserving the assumptions, rules and reasoning behind the resulting action.

4.1. BUILD-001 Builder Within Pricing Initiative

Every active Pricing Initiative must provide access to a Pricing Builder.

Pricing work created inside the builder must remain associated with:

- the initiative;
- affected pricing scope;
- current working version;
- creator and contributors;
- underlying pricing context;
- relevant analysis and scenarios.

The builder must not operate as a disconnected calculation tool.

4.2. BUILD-002 Pricing Action Definition

Users must be able to define the pricing action they are constructing.

Supported actions should include:

- set a new price;
- increase price;
- decrease price;
- apply a percentage adjustment;
- apply an absolute-value adjustment;

- maintain or protect a target margin;
- apply a markup;
- establish promotional pricing;
- markdown pricing;
- create pricing for a new product or service;
- define or modify a pricing rule;
- define a custom pricing action using supported builder components.

Quantitative pricing actions covered by ANALYSIS-002 must use the deterministic calculation definitions established in Section 3.5 where the required inputs are available.

New-product or service pricing, pricing rules and custom pricing actions may contain structured elements that are not themselves deterministically calculable.

The Builder must not represent a pricing outcome as deterministically calculated unless the required inputs, operators and calculation method are supported by the analytical calculation layer.

Where part of a pricing action depends on qualitative judgement, unsupported logic or a manually determined commercial value, that component must remain distinguishable from system-calculated quantitative output.

4.3. BUILD-003 Pricing Objective Context

The builder must display or inherit the Pricing Initiative's objective so that pricing logic is constructed within the intended business purpose.

Users must be able to see the relationship between:

objective → pricing logic → proposed action

A material change to the initiative objective must be reflected in the builder's working context.

4.4. BUILD-004 Scope-Aware Construction

Pricing logic must operate against an explicitly defined Pricing Scope.

The Builder must identify the Priceable Entities to which the pricing logic applies and the applicable pricing dimensions under which that logic applies.

Where the scope was established through a category, product group or another grouping selector, the Builder must preserve the selector while also making the resulting affected Priceable Entity set identifiable.

The Builder must clearly distinguish between:

- Priceable Entities receiving the pricing action;
- grouping selectors used to select those Priceable Entities;
- pricing dimensions qualifying where or how the pricing action applies.

Changes to category or group membership may alter the resolved working scope while the pricing work remains editable.

Once the pricing work is incorporated into a submitted Pricing Proposal, subsequent changes to category, group or workspace membership must not silently alter the controlled Proposal scope.

Users must not be able to submit pricing logic without knowing the commercial scope to which it applies.

4.5. BUILD-005 Structured Pricing Logic

The MVP must represent pricing logic using structured components rather than free-text instructions alone.

Supported Builder-owned components must include, where applicable:

- action;
- input;
- operator;
- value;
- condition;
- threshold contained within the pricing logic;
- initiative-specific constraint;
- effective period.

For example:

Increase current selling price by 8% provided resulting gross margin remains at or above 15%.

Where a condition or threshold is created specifically for the Pricing Initiative, it must remain an initiative-specific condition or constraint unless it references an existing organisational Guardrail configured under GOV-023.

Organisational Guardrails must not be created or redefined merely by including a threshold, condition or constraint in Builder pricing logic.

Where pricing work is subject to an organisational Guardrail, the Builder must reference the applicable Guardrail from the governance layer and consume its authoritative evaluation in accordance with BUILD-010 and ANALYSIS-014.

The underlying Builder structure must remain machine-readable while the user-facing representation remains understandable to business users.

4.6. BUILD-006 Human-Readable Representation

Every structured pricing rule or action must have a clear human-readable representation.

Relevant stakeholders must be able to understand:

- what will change;
- what determines the change;
- which entities are affected;
- which constraints apply;
- what happens when conditions are not satisfied.

Users must not need technical knowledge to review pricing logic.

4.7. BUILD-007 Supported Pricing Inputs

The builder must be able to reference supported pricing inputs available within the initiative, including where applicable:

- Current Price defined in DATA-003;
- applicable unit cost, including its cost basis where required for the pricing work;
- margin;
- markup;
- category;
- channel;
- location;

- effective date;
- manually entered variables;
- approved organisation parameters.

Unavailable inputs must not be fabricated or silently assumed.

Where pricing logic requires Current Price and the applicable Current Price is unavailable or unresolved for the affected pricing context, the Builder must identify that condition rather than silently selecting another Price Record.

The Builder must not use a price from another location, channel, customer group, price list, currency or other pricing context merely because a price exists for the same Priceable Entity.

Where pricing logic requires cost for a deterministic calculation, the Builder must use the Applicable Unit Cost defined in DATA-004 rather than selecting an arbitrary Cost Record.

Where more than one potentially applicable Cost Record exists and the applicable cost cannot be determined from the pricing context or organisation configuration, the pricing work must identify the ambiguity rather than silently selecting a cost value.

4.8. BUILD-008 Parameters and Assumptions

Users must be able to define parameters and assumptions used by the pricing logic.

Examples include:

- target margin;
- maximum allowable price increase;
- promotional discount;
- target markup;
- effective duration;
- assumed applicable unit cost, including the assumed cost basis;
- manually supplied commercial parameter.

The system must distinguish an assumption from a verified structured data value.

Where an assumed Applicable Unit Cost is used, the system must preserve that it is an assumption, the assumed amount, cost basis, currency and applicable unit of measure rather than representing it as a structured Cost Record.

4.9. BUILD-009 Conditions

Users must be able to add conditions determining when pricing logic applies.

Examples include:

- apply only to selected categories;
- apply only where margin falls below a defined threshold;
- apply only to a specific channel or location;
- apply during a defined promotional period.

Conditions must remain visible during review and the applicable organisational decision process.

4.10. BUILD-010 Guardrails and Initiative-Specific Constraints

Pricing work in the Builder must respect applicable organisational Guardrails and any separate initiative-specific constraints contained within the pricing work.

Organisational Guardrails must be sourced from the governance configuration defined in GOV-023.

The Builder must not independently create, redefine or modify an organisational Guardrail as part of ordinary pricing construction.

Where applicable Guardrails can be evaluated, the Builder must display the authoritative evaluation produced under ANALYSIS-014.

The Builder must make visible, where applicable:

- the applicable Guardrail;
- its evaluation state;
- the affected Priceable Entity or scope;
- the relevant threshold;
- the evaluated pricing value or metric;
- the configured behavioural treatment.

The Builder must distinguish organisational Guardrails from initiative-specific:

- conditions;
- commercial targets;

- assumptions;
- parameters;
- constraints.

An initiative-specific constraint must not automatically become an organisation-level Guardrail.

Where a required Guardrail cannot be evaluated because necessary information is unavailable, the Builder must display the resulting Unable to Evaluate state rather than treating the Guardrail as satisfied.

Changes to Builder pricing inputs or outputs that affect a Guardrail evaluation must cause the applicable analytical evaluation to be refreshed.

The Builder must not calculate or display an alternative Guardrail result that conflicts with ANALYSIS-014.

4.11. BUILD-011 Bulk Pricing Construction

The Builder must support pricing work affecting multiple Priceable Entities within the same Pricing Initiative.

Users should be able to apply common pricing logic across a selected Pricing Scope while preserving the resolved Priceable Entity set and applicable pricing dimensions.

Where the scope originates from a category, product group or another grouping selector, the common pricing logic must apply to the Priceable Entities resolved from that selector rather than treating the grouping itself as the price-bearing object.

The Builder must preserve entity-level visibility sufficient to identify:

- resulting pricing outcome;
- required inputs;
- applicable assumptions;
- guardrail result;
- exception status;
- missing or invalid information

for each affected Priceable Entity where those elements differ materially.

The MVP must not require users to manually recreate identical pricing logic for every SKU or other Priceable Entity included in the same logical pricing action.

4.12. BUILD-012 Entity-Level Exceptions

Where common pricing logic produces inappropriate results for specific entities, authorised users must be able to define exceptions.

An exception must identify:

- affected entity or sub-scope;
- deviation from the common logic;
- reason where required;
- resulting pricing action.

Exceptions must remain visible during review and the applicable organisational decision process.

4.13. BUILD-013 Calculation Preview

Before pricing work progresses into a formal Pricing Proposal or applicable organisational decision process, users must be able to preview the expected quantitative outcome of supported pricing logic against the available pricing scope.

Where applicable, the preview must identify:

- pricing action;
- calculation baseline;
- material calculation parameters;
- current price used, where current price is the applicable calculation or comparison baseline;
- deterministically derived or directly entered proposed selling price;
- absolute price change;
- percentage price change;
- applicable unit cost;
- cost basis used by the calculation;
- resulting gross profit;
- resulting gross margin;
- resulting markup;

- material assumptions used in the calculation;
- applicable guardrail status.

The preview must use the same deterministic calculation definitions as Section 3.5.

Where Current Price is used by the preview, it must be the Current Price resolved under DATA-003 for the applicable Priceable Entity and pricing context.

The preview must not silently substitute the newest, most recently imported or otherwise different Price Record where the applicable Current Price is unresolved or unavailable.

Where a pricing action or component cannot be deterministically evaluated, the preview must identify the affected calculation as unavailable rather than inventing or estimating a system-calculated result.

Where an explicit assumption is used, that assumption must remain distinguishable from verified organisational data.

The calculation preview is analytical working output and does not itself create organisational decision or execution authority.

4.14. BUILD-014 Missing or Invalid Calculation Input Handling

Where pricing logic depends on unavailable, invalid or incompatible information, the Builder must identify the affected requirement before presenting a deterministic calculation result.

The system must identify, where applicable:

- missing or invalid input;
- affected pricing action;
- affected calculation;
- affected priceable entities or pricing scope;
- whether the input may be supplied as an explicit assumption under organisational policy.

The system must not silently substitute invented values.

Users must be able to distinguish between:

- calculation completed using verified or structured inputs;
- calculation completed using an explicitly identified assumption;

- calculation unavailable because a required input is missing or invalid;
- calculation unavailable because the requested calculation method or operator is not supported.

An unavailable deterministic calculation must not be represented as zero, unchanged pricing or an AI-generated estimate.

Use of an explicit assumption must remain attributable and must follow the applicable assumption requirements.

4.15. BUILD-015 Draft State

Pricing logic remains in draft while it is being constructed.

Draft work may be edited by authorised contributors without entering a formal organisational decision path.

Submission for formal review or proposal creation establishes the relevant controlled version.

4.16. BUILD-016 Autosave and Working Continuity

The builder should preserve authorised user changes during active work to reduce loss of pricing work.

Users returning to an initiative must be able to continue from the latest valid working state.

Autosave must not overwrite previously submitted controlled versions or controlled versions associated with an Approved or Authorised Within Policy Pricing Proposal.

4.17. BUILD-017 Version Creation

The system must preserve controlled versions of pricing logic at consequential lifecycle points.

At minimum, a version must be identifiable when pricing work is:

- formally submitted for review where required;
- incorporated into a Pricing Proposal;
- materially revised after review;
- resubmitted following requested changes.

Previous controlled versions must remain retrievable.

4.18. BUILD-018 Consequential Builder Change Detection

Changes to Builder-owned pricing elements that materially affect the pricing outcome or decision basis must be treated as consequential changes.

Relevant Builder-owned elements may include:

- affected Pricing Scope;
- pricing action;
- manually embedded input values;
- assumptions;
- calculation logic;
- conditions;
- thresholds contained within the pricing logic;
- initiative-specific constraints;
- proposed pricing outputs.

A change to a Builder-owned element that changes an applicable Guardrail evaluation may therefore be consequential.

Organisational Guardrail configuration itself is not a Builder-owned pricing element.

Creation or modification of an organisational Guardrail must follow GOV-023 and GOV-034 rather than being represented as an ordinary Builder edit.

A change to organisational Guardrail configuration must not silently rewrite an existing Builder version or a submitted Pricing Proposal.

Where consequential Builder changes occur after formal Proposal submission, material-change and controlled-version treatment must follow PROP-017 rather than being independently defined by the Builder.

4.19. BUILD-019 AI-Assisted Construction

Users must be able to invoke AI assistance while constructing pricing work.

AI may help:

- translate business intent into structured pricing logic;

- draft pricing rules;
- explain existing logic;
- identify missing information;
- identify contradictory conditions;
- refine assumptions;
- propose alternative approaches;
- explain the likely effect of changes.

AI-generated changes must remain proposals until explicitly applied by an authorised human user.

4.20. BUILD-020 AI Change Visibility

When AI proposes a modification to existing pricing work, the user must be able to understand what is being changed before applying it.

The system must not silently replace user-authored pricing logic with AI-generated content.

Applied AI-assisted changes must become part of the attributable working history.

4.21. BUILD-021 Reusable Pricing Structures

Authorised users should be able to reuse appropriate pricing structures from previous work rather than rebuilding common pricing approaches from scratch.

Reusable Builder structures may include:

- pricing-rule structures;
- parameter sets;
- initiative-specific constraints;
- pricing logic structures;
- prior pricing approaches.

Reusing previous pricing work must create new editable working material.

Organisational Guardrail configurations must not be copied from historical pricing work into the Builder as independently editable pricing structures.

The Guardrails applicable to new pricing work must come from the governance configuration applicable to that new work under GOV-023.

Historical Guardrail information may remain visible as context where authorised, but historical Guardrail configuration must not silently replace currently applicable governance.

Previous approvals, policy authorisations or execution authority must not transfer to reused pricing work.

4.22. BUILD-022 Builder Validation

Before pricing work can become part of a formal Pricing Proposal, the Builder must validate that the Builder-owned pricing work is sufficiently defined for its intended pricing action.

Validation must include, where applicable:

- Pricing Scope exists;
- pricing action is defined;
- required calculation inputs are available or explicitly identified as assumptions;
- required operators and deterministic calculation methods are supported;
- numeric inputs satisfy applicable formula constraints;
- calculated outputs are valid;
- qualitative or non-deterministically evaluated components are explicitly distinguishable from calculated outputs;
- assumptions are explicit;
- initiative-specific conditions and constraints are sufficiently defined;
- applicable organisational Guardrails have been identified;
- authoritative Guardrail evaluations are available where the required analytical inputs exist;
- no unresolved Builder-owned validation error remains.

Where an applicable organisational Guardrail has been evaluated, the Builder must surface the ANALYSIS-014 result rather than calculate an alternative Guardrail result.

The Builder must not independently determine whether a Warning, Approval Escalation, Blocking Breach or Unable to Evaluate result permits formal Proposal submission.

Guardrail behavioural treatment is governed by GOV-025.

Formal Proposal submission readiness is governed by PROP-009.

The Builder must not treat unsupported custom logic as though it had been deterministically calculated.

Where non-deterministic pricing logic is permitted to progress, its manually determined, qualitative or unsupported components must remain explicit for subsequent analysis, review and organisational decision.

4.23. BUILD-023 Pricing Logic Provenance

The system must preserve who created or materially changed pricing logic and when.

Where relevant, the history must distinguish between:

- user-authored logic;
- AI-suggested logic applied by a user;
- reused logic originating from previous pricing work.

4.24. BUILD-024 Builder Output

The final output of the Pricing Builder is structured pricing work that can be consumed consistently by subsequent MVP capabilities.

Where applicable, the Builder output must preserve:

- pricing action;
- affected pricing scope;
- relevant pricing baseline;
- structured pricing logic;
- calculation inputs;
- explicit assumptions;
- material parameters;
- conditions;
- constraints;
- references to applicable organisational Guardrails and, where available, their authoritative ANALYSIS-014 evaluation results;
- exceptions;
- deterministic calculation status;
- applicable calculation method;
- resulting proposed pricing output;
- distinction between system-calculated values and manually determined or qualitative components.

Organisational Guardrail references contained in Builder output must point to the applicable governance-defined Guardrail rather than represent a separately authored Builder Guardrail.

Where an ANALYSIS-014 evaluation is not yet available, the Builder output may preserve the applicable Guardrail reference without inventing an evaluation result.

For deterministically calculable pricing work, the Builder output must contain sufficient information for the analytical layer to reproduce the result using the calculation definitions in Section 3.5.

For pricing work that contains non-deterministic components, the output must preserve those components without falsely converting them into calculated quantitative results.

The Builder output must provide sufficient information for:

- pricing analysis;
- Scenario evaluation;
- collaboration;
- review;
- Pricing Proposal creation;
- organisational decision;
- execution preparation;
- historical understanding.

The Pricing Builder therefore serves as the controlled bridge between a business pricing objective and the specific pricing action ultimately submitted for organisational decision.

3.5 Pricing Analysis and Scenario Evaluation

5. PRICING ANALYSIS AND SCENARIO EVALUATION

The MVP must provide a structured analytical environment for evaluating the financial and commercial implications of pricing work before it is submitted for decision.

The purpose of this capability is not advanced optimisation. It is to ensure that users can understand the likely effect of a proposed pricing action using available organisational data, explicit assumptions and comparable scenarios.

5.1. ANALYSIS-001 Initiative-Level Analysis

Every Pricing Initiative must provide an analysis area connected to:

- the affected pricing scope;
- current pricing data;
- relevant cost records and the applicable unit cost selected or assumed for the analysis;
- pricing logic;
- assumptions;
- scenarios;
- applicable guardrails.

Analysis must remain part of the Pricing Initiative rather than exist as a disconnected calculator.

5.2. ANALYSIS-002 Deterministic Pricing Calculation Coverage

Where the required inputs are available, the MVP must provide deterministic calculation support for the quantitative pricing actions defined in the Pricing Builder.

The analytical calculation layer must support, where applicable:

- direct entry of a proposed selling price;
- percentage increase or decrease from a defined baseline price;
- absolute-value increase or decrease from a defined baseline price;
- derivation of a selling price from a target gross-margin percentage;
- derivation of a selling price from a target markup percentage;
- promotional or discount pricing expressed as a percentage reduction;

- promotional or discount pricing expressed as an absolute-value reduction;
- markdown pricing expressed through a supported percentage or absolute-value adjustment;
- calculation of the resulting selling price from supported structured pricing logic where all required inputs and operators are deterministically evaluable.

For the current and resulting proposed pricing position, the MVP must calculate or preserve, where applicable:

- current selling price;
- proposed selling price;
- absolute price change;
- percentage price change;
- applicable unit cost;
- gross profit per unit;
- gross margin percentage;
- markup percentage.

A pricing action must not be presented as deterministically calculated where the system does not have sufficient inputs or a supported calculation method to derive its result.

Pricing approaches that contain qualitative judgement, unsupported custom logic or conditions that cannot be deterministically evaluated may still be represented within the Pricing Initiative, but the system must distinguish those elements from calculated quantitative outputs.

The same calculation definitions must be used consistently across the Pricing Builder preview, pricing analysis, Scenarios, Proposal preparation and guardrail evaluation.

AI must not independently define or alter these deterministic calculation methods.

5.3. ANALYSIS-003 Gross Profit Calculation

Where:

Selling Price = P

Applicable Unit Cost = C

gross profit per unit must be calculated as:

Gross Profit per Unit = P - C

The value represented by C must be the Applicable Unit Cost defined in DATA-004.

The Selling Price and Applicable Unit Cost used in the calculation must have compatible currencies and compatible units of measure.

For every consequential gross-profit calculation, the system must preserve enough information to identify:

- selling price used;
- Applicable Unit Cost used;
- cost basis;
- currency;
- applicable unit of measure;
- source Cost Record or explicit cost assumption;
- relevant effective context.

Where no valid Applicable Unit Cost can be identified, the system must not present gross profit per unit as deterministically calculated.

The calculation engine must not independently infer, average or construct an alternative cost value in place of the Applicable Unit Cost.

5.4. ANALYSIS-004 Gross Margin and Target-Margin Price Calculation

Where the selling price and the Applicable Unit Cost defined in DATA-004 are available, the gross margin percentage must be calculated as:

Gross Margin % = ((Selling Price - Applicable Unit Cost) / Selling Price) × 100

This calculation is valid only where Selling Price is greater than zero.

The system must distinguish gross margin from markup.

Where a user defines a target gross-margin percentage and the Applicable Unit Cost defined in DATA-004 is available and greater than zero, the system must deterministically derive the corresponding proposed selling price as:

Proposed Selling Price = Applicable Unit Cost / (1 - (Target Gross Margin % / 100))

The target gross-margin percentage used in this calculation must be less than 100%.

Where the target gross-margin percentage is equal to or greater than 100%, or the required Applicable Unit Cost is unavailable or invalid, the system must not produce a derived proposed selling price and must identify why the calculation cannot be completed.

Where organisational policy permits a negative target gross margin, the calculation may proceed provided the required inputs are valid and the resulting price satisfies applicable guardrails.

The system must preserve the Applicable Unit Cost, cost basis, source Cost Record or explicit cost assumption, target gross-margin percentage, formula and resulting unrounded proposed selling price used in the calculation.

Any displayed or executable price rounding must follow the applicable pricing precision and rounding rules rather than silently changing the underlying target-margin calculation.

5.5. ANALYSIS-005 Markup and Target-Markup Price Calculation

Where selling price and the Applicable Unit Cost defined in DATA-004 are available and Applicable Unit Cost is greater than zero, markup percentage must be calculated as:

Markup % = ((Selling Price - Applicable Unit Cost) / Applicable Unit Cost) × 100

The system must distinguish markup from gross margin.

Where a user defines a target markup percentage and the Applicable Unit Cost defined in DATA-004 is available and greater than zero, the system must deterministically derive the corresponding proposed selling price as:

Proposed Selling Price = Applicable Unit Cost × (1 + (Target Markup % / 100))

A target markup below -100% must not produce a derived proposed selling price because it would result in a negative selling price.

Where organisational policy permits a negative target markup of -100% or greater, the calculation may proceed provided the resulting proposed price and pricing economics satisfy applicable validation and guardrail requirements.

Where the required Applicable Unit Cost is unavailable, invalid or equal to zero, the system must not represent the target-markup price as deterministically calculated and must identify why the calculation cannot be completed.

The system must preserve the Applicable Unit Cost, cost basis, source Cost Record or explicit cost assumption, target markup percentage, formula and resulting unrounded proposed selling price used in the calculation.

Any displayed or explicitly applied price rounding must follow ANALYSIS-023 and must not silently change the underlying target-markup calculation.

5.6. ANALYSIS-006 Price Adjustment and Price Change Calculation

Where a pricing action derives a proposed selling price from a baseline price, the baseline used by the calculation must be explicitly identifiable.

The baseline may be the current selling price or another supported pricing baseline explicitly defined by the pricing action.

Where the baseline is Current Price, the calculation must use the Current Price defined in DATA-003 for the affected Priceable Entity and pricing context.

Where no unambiguous Current Price exists, the system must not silently select another Price Record as Current Price.

An authorised user may define another supported pricing baseline where the pricing action permits it, but that baseline must remain explicitly distinguishable from Current Price.

Where:

Baseline Price = B

Percentage Adjustment = R

Absolute Adjustment = A

the MVP must support the following deterministic calculations where applicable.

For a percentage increase:

Proposed Selling Price = B × (1 + (R / 100))

For a percentage decrease:

Proposed Selling Price = B × (1 - (R / 100))

For an absolute-value increase:

Proposed Selling Price = B + A

For an absolute-value decrease:

Proposed Selling Price = B - A

For promotional, discount or markdown pricing expressed as a percentage reduction:

Proposed Selling Price = B × (1 - (Discount % / 100))

For promotional, discount or markdown pricing expressed as an absolute-value reduction:

Proposed Selling Price = B - Discount Amount

Percentage reductions must not be less than 0% or greater than 100%.

Absolute reductions must not produce a negative proposed selling price.

Where a promotional, markdown or other pricing action directly specifies the final selling price rather than an adjustment, that value must be treated as the proposed selling price rather than recalculated through an adjustment formula.

After the proposed selling price is determined, the system must calculate price change against Current Price where an unambiguous Current Price is available under DATA-003.

Where Current Price is available:

Absolute Price Change = Proposed Price - Current Price

and, where Current Price is not zero:

Price Change % = ((Proposed Price - Current Price) / Current Price) × 100

Where Current Price is zero, percentage price change must be represented as unavailable rather than producing an undefined or misleading percentage.

Where Current Price is unavailable or unresolved, absolute and percentage change against Current Price must be represented as unavailable.

Unavailability of Current Price must not prevent a pricing action from being deterministically calculated where that action validly uses another explicitly identified pricing baseline and all inputs required for that calculation are available.

Where the product displays a change relative to an alternative pricing baseline, that result must be explicitly identified as change relative to that baseline and must not be labelled as change from Current Price.

The system must preserve the pricing action, baseline value, baseline type, adjustment value, calculation method and resulting proposed selling price used in the calculation.

Where Current Price is the baseline, the preserved calculation context must remain traceable to the exact source Price Record defined under DATA-003.

5.7. ANALYSIS-007 Current and Proposed Economics

Analysis must clearly distinguish between:

Current State

and

Proposed State

Where data permits, the system should display both side by side for relevant metrics including:

- price;
- gross profit;
- gross margin;
- markup.

The user must not have to manually reconstruct the economic difference between current and proposed pricing.

Where Current State includes a selling price, that price must be the Current Price determined under DATA-003 for the applicable Priceable Entity and pricing context.

Where Current Price is unavailable or unresolved, the system must not silently use another Price Record and represent it as Current State.

Where an alternative pricing baseline is used for analytical comparison, that baseline must remain explicitly distinguishable from Current State.

Current-state financial metrics that depend on Current Price must be represented as unavailable where the required Current Price or other required financial input cannot be validly determined.

5.8. ANALYSIS-008 Scenario Creation

Authorised users must be able to create multiple pricing scenarios within an initiative.

A scenario represents an alternative pricing approach under consideration.

Each scenario should contain, where relevant:

- name;
- pricing action;
- proposed price or pricing logic;
- assumptions;
- affected scope;
- calculated outputs;
- guardrail status;
- creator;
- timestamp.

5.9. ANALYSIS-009 Scenario Independence

Scenarios must remain exploratory until deliberately selected for further progression.

Creating or modifying a scenario must not:

- modify the current live price;
- create an approval;
- replace an approved proposal;
- trigger execution.

5.10. ANALYSIS-010 Scenario Comparison

Users must be able to compare scenarios using relevant measures.

Where inputs are available, comparison should include:

- proposed price;
- price change;
- gross profit;
- gross margin;
- markup;
- applicable guardrail status;
- material assumptions.

Scenario comparison must make trade-offs visible rather than presenting only a recommended option.

5.11. ANALYSIS-011 Baseline Scenario

Where an unambiguous Current Price exists under DATA-003, the existing pricing position should serve as the default baseline against which alternative Scenarios can be compared.

The baseline must use the Current Price applicable to the same Priceable Entity and pricing dimensions being evaluated.

Where the relevant Current Price is unavailable or unresolved, the system must not fabricate a baseline or silently use a Price Record from another pricing context.

Where supported, an authorised user may explicitly define another pricing baseline for analytical comparison.

An explicitly defined alternative baseline must remain distinguishable from Current Price and must preserve its source or assumption basis.

Users must be able to understand whether a proposed Scenario improves, worsens or maintains relevant economic measures compared with the identified baseline.

5.12. ANALYSIS-012 Scope-Level Analysis

For Pricing Initiatives affecting multiple Priceable Entities, analysis must support both:

- aggregate visibility where meaningful;
- Priceable Entity-level results.

Aggregate analysis may be grouped using relevant categories, product groups or pricing dimensions.

Aggregation by a category, product group or pricing dimension must not cause that grouping to be represented as the underlying Priceable Entity.

Users must remain able to determine which Priceable Entities contribute to an aggregate result.

Aggregate results must not conceal Priceable Entity-level guardrail breaches, missing inputs, exceptions or materially negative outcomes.

5.13. ANALYSIS-013 Priceable Entity-Level Outcomes

Where common pricing logic applies across multiple Priceable Entities, the system should calculate or preserve the resulting outcome for each applicable Priceable Entity where the required inputs are available.

Each entity-level outcome must remain associated with the applicable pricing dimensions relevant to that outcome.

Users must be able to identify:

- Priceable Entities that satisfy the proposed logic;
- Priceable Entities that breach guardrails;
- Priceable Entities missing required inputs;
- Priceable Entities producing exceptional outcomes;
- Priceable Entities for which the pricing action cannot be deterministically evaluated.

Where the Pricing Scope was established using a category, product group or another grouping selector, the entity-level analysis must operate on the resolved Priceable Entities rather than producing a single artificial price-bearing result for the grouping itself.

5.14. ANALYSIS-014 Deterministic Guardrail Evaluation

The analytical layer must perform deterministic evaluation of applicable organisational Guardrails defined under GOV-023 where the required structured pricing information is available.

The analytical layer must not independently create Guardrails, determine Guardrail applicability or redefine their configured behavioural treatment.

Those responsibilities remain governed by GOV-023, GOV-024 and GOV-025.

For each applicable Guardrail, supported evaluation states must include:

- Within Guardrail;
- Breach;
- Unable to Evaluate.

Near Threshold may additionally be displayed only where the applicable Guardrail configuration defines a supported proximity threshold or warning band sufficient to determine that state consistently.

Near Threshold must not be inferred from an undefined or arbitrary proximity rule.

Each material Guardrail evaluation must preserve enough information to determine, where applicable:

- Guardrail identifier;
- applicable Guardrail configuration version;
- affected Priceable Entity or Pricing Scope;
- applicable pricing dimensions;
- metric or pricing condition evaluated;
- operator or comparison rule;
- configured threshold or value;
- actual pricing value or calculated metric evaluated;
- relevant source inputs or assumptions;
- evaluation state;
- evaluation timestamp.

Where required information is missing, invalid or incompatible, the evaluation state must be Unable to Evaluate.

Unable to Evaluate must not be represented as Within Guardrail.

The analytical layer must return the evaluation result to the consuming product capabilities.

The governance consequence of a Breach must follow the behavioural treatment configured under GOV-025 rather than being independently determined by the analytical layer.

Where multiple Guardrails apply to the same pricing work, each Guardrail must be evaluated and preserved separately.

Aggregate analysis must not conceal an entity-level Guardrail Breach or Unable to Evaluate result.

5.15. ANALYSIS-015 Margin Floor Validation

Where an organisation has configured a minimum gross-margin threshold, the system must evaluate the proposed selling price against that threshold using the Applicable Unit Cost defined in DATA-004.

The margin-floor evaluation must use the same Applicable Unit Cost and cost basis as the decision-relevant gross-margin analysis for that pricing action.

Where no valid Applicable Unit Cost is available, or where the applicable cost cannot be determined because multiple Cost Records remain unresolved, the margin-floor guardrail must be represented as Unable to Evaluate rather than as passed or breached.

Where an explicit assumed Applicable Unit Cost is permitted and used, that assumption must remain visible and attributable during the guardrail evaluation.

A confirmed breach must remain visible during:

- analysis;
- review;
- Proposal creation;
- the applicable organisational decision process.

The system must not hide a breach because the Proposal is otherwise complete.

A change to the Applicable Unit Cost or cost basis that materially changes the margin-floor result must be treated as a consequential change to the decision basis.

5.16. ANALYSIS-016 Missing Data

Where an analysis cannot be completed because required information is unavailable, the system must identify:

- missing field or input;
- affected calculation;

- affected entities where applicable.

The system must not fabricate missing values.

5.17. ANALYSIS-017 Explicit Assumption Use

Users may provide an explicit assumption where verified information is unavailable and organisational policy permits its use.

An assumption used in analysis must be:

- clearly marked;
- attributable;
- visible during review;
- preserved with the relevant proposal version.

Assumed values must not be represented as verified organisational data.

5.18. ANALYSIS-018 Manual Scenario Inputs

Authorised users must be able to enter scenario-specific values where appropriate.

Examples include:

- assumed applicable unit cost, including the assumed cost basis;
- proposed discount;
- target price;
- target margin;
- manually estimated commercial outcome.

Manual scenario inputs must be identified as user-supplied values.

Where an assumed Applicable Unit Cost is used in a Scenario, the system must preserve the assumed amount, cost basis, currency and applicable unit of measure and must distinguish that assumption from a structured Cost Record in accordance with DATA-004 and ANALYSIS-017.

5.19. ANALYSIS-019 Qualitative Decision Inputs

The analysis area must be able to reference qualitative decision inputs that materially affect interpretation of pricing work but are not deterministic calculation outputs.

Qualitative decision inputs may originate from:

- structured Pricing Context governed by Section 3.2;
- Evidence governed by Section 3.7;
- explicit Assumptions governed by ANALYSIS-017;
- attributable user-authored analytical interpretation.

Relevant examples may include:

- competitor observations;
- customer or sales feedback;
- supplier information;
- market conditions;
- operational constraints;
- commercial judgement.

The analytical layer must preserve the originating information type rather than creating a separate competing qualitative-context object.

Analysis must not:

- represent Evidence as verified structured organisational data;
- represent an Assumption as a verified fact;
- represent user interpretation as Evidence;
- represent AI interpretation as recorded organisational fact;
- convert a qualitative input into a deterministic calculation output merely because it influenced the analysis.

Where a qualitative decision input materially supports a submitted Pricing Proposal, the Proposal and historical record must preserve sufficient reference to its originating information type and relevant source or version context.

5.20. ANALYSIS-020 AI-Assisted Analysis

Users must be able to invoke AI to assist in interpreting the available pricing analysis.

AI may:

- explain calculations;
- summarise differences between scenarios;

- identify material trade-offs;
- identify missing information;
- surface inconsistencies;
- explain guardrail breaches;
- highlight potentially consequential assumptions;
- help users formulate additional scenarios.

AI-generated interpretation must not alter underlying calculations.

5.21. ANALYSIS-021 AI Recommendation Boundary

AI may identify or suggest a scenario for consideration, but it must not present an unverified suggestion as an authoritative pricing decision.

Where AI recommends an option, the user should be able to understand the available basis for that recommendation.

Selection of a scenario remains a human action.

5.22. ANALYSIS-022 Calculation Traceability

Users must be able to understand and reproduce the basis of consequential deterministic pricing calculations.

For each material calculated output, the MVP must preserve enough calculation context to determine, where applicable:

- pricing action;
- affected pricing object or scope;
- calculation baseline;
- source input values;
- source of those values;
- explicitly assumed values;
- calculation parameter or adjustment value;
- operator;
- formula or deterministic calculation method used;
- resulting unrounded calculated value;
- explicitly applied rounding or final-value adjustment, where applicable;
- resulting proposed value used by subsequent pricing work.

A calculated output must remain distinguishable from a directly entered value, explicit assumption or manually determined commercial value.

Calculation traceability must remain consistent across the Pricing Builder, analysis, Scenarios, Proposal preparation and guardrail evaluation.

Pricing analysis must therefore be reproducible from the preserved decision-relevant pricing context.

5.23. ANALYSIS-023 Calculation Precision and Rounding

The system must use sufficient internal numeric precision to avoid material pricing errors caused by premature rounding.

Deterministic calculations must operate on underlying stored values rather than repeatedly calculating from rounded display values.

Where a formula produces a value with greater precision than is appropriate for display, the system must preserve the underlying calculated value separately from its formatted display representation.

Display formatting must not silently alter the underlying calculated proposed price.

Where a user or supported organisational rule explicitly applies commercial price rounding, the system must preserve, where applicable:

- the pre-rounding calculated price;
- the rounding method or explicitly selected rounded value;
- the resulting proposed price after rounding.

Where the rounded proposed price becomes the actual pricing value proposed for organisational decision, downstream gross profit, gross margin, markup, price-change calculations and guardrail evaluations must use that resulting proposed price.

The system must not imply that a rounded proposed price still achieves an exact target margin or markup where rounding causes the resulting economics to differ.

Automatic psychological-pricing optimisation, charm-price generation or other advanced price-ending optimisation is not required for the MVP.

5.24. ANALYSIS-024 Currency Consistency

Calculations involving monetary values must use compatible currencies.

Where values are supplied in different currencies and the MVP does not have an approved conversion input, the system must not automatically combine them.

A user-provided exchange rate may be used as an explicit assumption where permitted.

The assumed rate, source and relevant date should be preserved with the pricing work.

5.25. ANALYSIS-025 Scenario Selection

An authorised user must be able to designate one scenario or pricing approach as the selected basis for the proposed action.

Selection must not itself constitute approval.

The selected scenario becomes the basis from which the relevant Pricing Proposal can be constructed.

5.26. ANALYSIS-026 Analytical Completeness for Proposal Preparation

Before analysed pricing work is used to prepare a formal Pricing Proposal, the analytical layer must determine whether the decision-relevant analysis is sufficiently complete to support Proposal preparation.

The analytical completeness check must identify, where applicable:

- unresolved calculation errors;
- missing required financial inputs;
- calculations that remain unavailable;
- invalid pricing outputs;
- material assumptions that are undefined or insufficiently identified;
- applicable Guardrails that remain Unable to Evaluate because required analytical information is missing or invalid.

A Guardrail Breach is an analytical evaluation result and must not automatically be represented as an analytical error.

The governance consequence of a Guardrail Breach is determined by the configured behavioural treatment under GOV-025.

The analytical layer must not independently determine whether a Pricing Proposal may be submitted.

Formal Proposal submission readiness, including treatment of Warning, Approval Escalation, Blocking and Unable to Evaluate Guardrail results, is governed by PROP-009.

Analytical completeness must therefore supply authoritative analysis and Guardrail evaluation information to Proposal readiness without becoming a second owner of submission policy.

5.27. ANALYSIS-027 Analysis Snapshot

When a Pricing Proposal is submitted, the decision-relevant analysis supporting that Proposal version must be preserved.

Where cost-dependent calculations form part of the analysis, the preserved analysis must retain, where applicable:

- the Applicable Unit Cost used;
- cost basis;
- currency;
- applicable unit of measure;
- source Cost Record or explicit cost assumption;
- relevant effective context;
- calculated financial outputs dependent on that cost.

Subsequent changes to:

- Cost Records;
- selection of the Applicable Unit Cost;
- cost basis;
- current prices;
- assumptions;
- Scenarios;
- underlying workspace data

must not silently modify, recalculate or reinterpret the analysis associated with an already submitted Proposal version.

Where an explicit assumed Applicable Unit Cost formed part of the submitted analysis, that value must remain identifiable as an assumption rather than verified organisational cost data.

Historical analysis must continue to reflect the exact cost context and other decision-relevant inputs used when the Proposal version was submitted.

5.28. ANALYSIS-028 Historical Analysis

Users reviewing previous Pricing Initiatives must be able to inspect the analysis and scenarios that informed the decision at the time.

Historical analysis must preserve the original inputs and outputs rather than recalculating history using current values.

5.29. ANALYSIS-029 Analysis Export

Authorised users should be able to export relevant analysis associated with a Pricing Initiative or proposal in a structured form.

The exported information must respect:

- data-access permissions;
- restricted cost visibility;
- proposal versioning;
- historical integrity.

5.30. ANALYSIS-030 Analytical Completeness Principle

The MVP must provide enough analytical capability for a pricing team to determine:

What is the current economic position?
What are we proposing to change?
What does that change do to the economics?
Which assumptions are we relying on?
Which guardrails are affected?
What alternatives were considered?

If those questions cannot be answered from the Pricing Initiative before submission, the pricing work is not decision-ready.

3.6 Pricing Proposal Management

6. PRICING PROPOSAL MANAGEMENT

The Pricing Proposal is the formal decision object through which developed pricing work is presented for organisational review, approval or policy authorisation.

A Pricing Proposal must represent the specific pricing action the organisation is being asked to decide on. It must remain distinct from the broader Pricing Initiative, exploratory Scenarios and editable working material inside the Pricing Builder.

The MVP must preserve a clear relationship between:

Pricing Initiative → Pricing Work and Analysis → Pricing Proposal → Organisational Decision → Execution

The Pricing Initiative remains the primary container for the complete body of pricing work. The Pricing Proposal represents the exact action submitted for decision.

6.1. PROP-001 Pricing Proposal Definition

A Pricing Proposal must represent a specific proposed pricing action associated with one Pricing Initiative.

The Proposal must answer, at minimum:

- what pricing action is being proposed;
- which priceable entities and pricing dimensions are affected;
- what the relevant current or baseline pricing position is;
- what the proposed pricing position or rule is;
- why the action is being proposed;
- what material assumptions support it;
- what analysis supports the action;
- which applicable guardrails were evaluated;
- when the proposed action should become effective.

A Pricing Proposal must not represent the entire Pricing Initiative.

6.2. PROP-002 Initiative Relationship

Every Pricing Proposal must belong to exactly one Pricing Initiative.

The Pricing Initiative must preserve the relationship between the Proposal and the underlying:

- pricing objective;
- pricing scope;
- pricing context;
- Pricing Builder work;
- pricing logic;
- analysis;
- Scenarios where applicable;
- assumptions;
- evidence;
- collaboration;
- workflow;
- organisational decision records, including approvals and policy authorisations;
- execution records.

A Pricing Proposal must not exist as disconnected pricing work outside its originating Pricing Initiative.

6.3. PROP-003 Proposal Creation

An authorised user must be able to create a Pricing Proposal from sufficiently developed pricing work within a Pricing Initiative.

Proposal creation may use:

- pricing work constructed directly in the Pricing Builder;
- a Scenario deliberately selected as the basis for progression;
- another supported pricing approach developed within the Initiative.

Creating a Pricing Proposal must create the initial Proposal version in Draft status.

The Draft Proposal version may be edited by authorised users until it is formally submitted into an applicable organisational decision path.

Formal submission must freeze that same Draft Proposal version as the controlled decision package used for either item-level approval or configured policy authorisation.

Submission must not create a second Proposal version solely because the existing Draft Proposal version enters a decision path.

Proposal creation must not by itself:

- submit the Proposal into an organisational decision path;
- create an approval;
- provide policy authorisation;
- authorise execution;
- modify the organisation's current price;
- trigger implementation.

6.4. PROP-004 Current Proposal

For the MVP, a Pricing Initiative must have no more than one current Pricing Proposal progressing through the active decision and execution path at a time.

The Initiative may retain:

- previous Proposal versions;
- rejected Proposal versions;
- superseded Proposal versions;
- expired Proposal versions;
- exploratory Scenarios;
- historical pricing work.

The system must clearly identify which Pricing Proposal and version is currently applicable to the Initiative.

6.5. PROP-005 Proposal Identification

Every Pricing Proposal must have a persistent identifier within its Pricing Initiative.

Every controlled Proposal version must also have a unique version identifier.

The system must preserve, at minimum:

- Proposal identifier;
- Proposal version;
- originating Pricing Initiative;

- current or historical status;
- creator;
- creation timestamp;
- submitting user where applicable;
- submission timestamp where applicable.

Users must be able to distinguish the current Proposal version from previous versions.

6.6. PROP-006 Proposal Content

Before formal submission, the Pricing Proposal must contain sufficient information for an authorised reviewer or approver to understand the proposed pricing decision without reconstructing it from disconnected parts of the Initiative.

Where applicable, the Proposal must contain or reference:

- affected pricing scope;
- current or baseline pricing state;
- proposed pricing action;
- proposed prices or pricing logic;
- relevant currency;
- pricing objective;
- supporting rationale;
- material assumptions;
- relevant analysis and calculated outputs;
- applicable guardrail evaluation;
- material exceptions;
- relevant supporting evidence;
- intended effective date or effective period;
- relevant implementation information required for operational handoff.

Information referenced from another Initiative object must remain bound to the exact version used by the Proposal.

6.7. PROP-007 Proposal Source Traceability

The Proposal must preserve traceability to the pricing work from which it was created.

Where applicable, users must be able to determine:

- which Pricing Builder logic produced the proposed action;
- which Scenario was selected;
- which calculations informed the Proposal;
- which assumptions were used;
- which pricing-context values were relied upon;
- which evidence supported the rationale;
- which guardrails were evaluated.

The system must not silently replace these sources after the Proposal has been submitted.

6.8. PROP-008 Scenario and Proposal Separation

A Scenario and a Pricing Proposal must remain separate product objects.

A Scenario represents an alternative pricing approach under consideration.

A Pricing Proposal represents the specific action being submitted for organisational decision.

Selecting a Scenario may establish it as the basis for Proposal creation, but Scenario selection must not itself:

- create approval or policy-authorisation authority;
- make the Scenario an authorised pricing action;
- trigger execution;
- replace the formal Proposal process.

A Pricing Proposal may also be created without a Scenario where the pricing action was developed directly through the Pricing Builder.

6.9. PROP-009 Proposal Readiness

Before a Pricing Proposal can be formally submitted, the system must determine whether the Proposal is sufficiently complete for organisational decision.

Readiness must consider applicable requirements including:

- defined Pricing Scope;
- defined pricing action;
- valid pricing logic;
- required pricing inputs;

- required analysis;
- explicit material assumptions;
- applicable Guardrail evaluations produced under ANALYSIS-014;
- configured Guardrail behavioural treatment under GOV-025;
- required effective timing;
- unresolved blocking errors;
- required organisational decision information.

Proposal readiness must consume the authoritative Guardrail evaluation and configured behavioural treatment rather than independently recalculating or redefining Guardrail status.

Where an applicable Guardrail result is Breach:

- Warning treatment may permit submission where all other readiness requirements are satisfied, but the Breach must remain visible;
- Approval Escalation treatment must preserve the requirement for the applicable escalated organisational decision path;
- Blocking treatment must prevent submission where the applicable controlled gate does not permit progression.

Where a Guardrail required for the organisational decision is Unable to Evaluate, the Proposal must not be treated as ready unless the applicable organisational policy explicitly permits progression without that evaluation.

Missing or blocking readiness requirements must be clearly identified to the user.

A Proposal that fails a blocking readiness requirement must not be submitted.

Proposal readiness must not independently redefine Guardrail configuration, evaluation logic, approval authority or policy-authorisation eligibility.

6.10. PROP-010 Draft Proposal

A newly created Pricing Proposal must begin as Draft.

A Draft Proposal may be edited by authorised users according to their permissions.

Draft status must indicate that the Proposal:

- has not yet entered a formal organisational decision path;
- does not represent an authorised pricing decision;

- does not grant execution authority.

Changes made while the Proposal remains an unsubmitted Draft must not create approval or policy-authorisation records.

6.11. PROP-011 Proposal Submission and Decision Snapshot

When a Pricing Proposal is formally submitted into an applicable organisational decision path, the system must freeze the current Draft Proposal version as the controlled decision snapshot representing the exact decision package presented for item-level approval or policy authorisation.

Formal submission must not create an additional Proposal version solely because the existing Draft Proposal version entered the decision process.

The submitted Proposal version must preserve, where applicable:

- Proposal identifier and version;
- originating Pricing Initiative;
- organisational decision path;
- exact resolved affected Pricing Scope, including the Priceable Entities and applicable pricing dimensions covered by the submitted Proposal version;
- current or baseline pricing state used;
- decision-relevant pricing context governed by DATA-013, including the Applicable Unit Cost and cost basis where cost-dependent analysis informed the Proposal;
- proposed pricing action;
- proposed prices or pricing logic;
- material assumptions;
- decision-relevant analysis;
- calculated outputs;
- applicable Guardrail identifiers, configuration versions, configured behavioural treatments and ANALYSIS-014 evaluation results;
- material exceptions;
- supporting evidence references;
- intended effective date or effective period;
- submitting user;
- submission timestamp;
- applicable workflow, approval or policy-authorisation requirements;

- applicable policy and qualification evaluation where a policy-authorisation path is used.

Subsequent changes to underlying workspace data must not silently modify, recalculate or reinterpret the submitted Proposal version or its decision snapshot.

The Guardrail information preserved with the submitted Proposal version must represent the exact Guardrail configuration and evaluation that formed part of the decision package at submission.

Subsequent creation, modification, activation, deactivation or replacement of an organisational Guardrail must not silently change the Guardrail configuration, behavioural treatment or evaluation preserved with that submitted Proposal version.

Where the organisation requires a changed Guardrail configuration to become part of the decision basis for already submitted pricing work, that treatment must be explicit and must follow the applicable material-change and controlled-version requirements.

Where a category, product group or another grouping selector was used to establish the Pricing Scope, the submitted Proposal version must preserve both the selector used and the exact Priceable Entity set resolved at submission.

Subsequent changes to category membership, product-group membership or other grouping relationships must not add Priceable Entities to, remove Priceable Entities from or otherwise change the affected scope of the already submitted Proposal version.

A material change after submission must follow PROP-017.

Any approval or policy authorisation must bind to this exact controlled Proposal version in accordance with PROP-021.

6.12. PROP-012 Proposal Status

The MVP must support the following Pricing Proposal statuses:

- Draft;
- Awaiting Approval;
- Changes Requested;
- Rejected;
- Approved;

- Authorised Within Policy.

These statuses represent the decision-processing condition of the applicable Proposal version.

Formal submission into an item-level approval workflow must change the applicable controlled Proposal version from Draft to Awaiting Approval.

Where a current Draft Proposal version is instead validly authorised through a configured policy-authorisation path, that same controlled Proposal version must change from Draft to Authorised Within Policy in accordance with the applicable policy and governance requirements.

A Proposal version must not simultaneously be represented as Awaiting Approval and Authorised Within Policy.

Where policy authorisation is not granted and item-level approval is required, the Proposal must enter Awaiting Approval when it is submitted into the applicable approval workflow.

Execution states such as Implemented must not be represented as Proposal statuses.

Pricing Initiative lifecycle states must remain separate from Pricing Proposal statuses.

6.13. PROP-013 Proposal Version Validity

The system must separately identify whether a Proposal version is currently applicable, has been superseded or has expired.

Applicable Proposal version validity states are:

- Current;
- Superseded;
- Expired.

Proposal version validity must remain separate from Proposal status.

Current means that the version is the presently applicable Proposal version within the Pricing Initiative. It does not by itself mean that the Proposal is approved, authorised or executable.

Superseded means that another Proposal version has replaced it as the currently applicable version.

Expired means that the Proposal version is no longer valid for current progression or execution because its applicable validity period, effective window or organisational validity condition has ended.

A Proposal version's validity state must not overwrite the historical Proposal status or decision recorded against that version.

For example, an Approved Proposal that later expires must remain historically identifiable as Approved while also being identifiable as Expired.

6.14. PROP-014 Approval Progress

Where a Pricing Proposal requires multiple approvals, the system must distinguish approval progress from Proposal decision status.

The system may identify approval progress such as:

- approvals completed;
- approvals outstanding;
- current approval stage.

Partial completion of a required approval chain must not create a separate Proposal decision state.

The Proposal must remain Awaiting Approval until the applicable decision requirements are resolved.

6.15. PROP-015 Changes Requested

When Changes Requested is recorded against a Proposal version:

- the affected Proposal version must remain preserved;
- the requesting user must be identifiable;
- the request timestamp must be preserved;
- the requested change or associated comment must remain attached to the relevant version;
- the Proposal version must leave active approval progression;

- the Pricing Initiative must return to the appropriate development or review state.

A materially revised Proposal must be submitted as a new controlled version.

6.16. PROP-016 Rejected Proposal

When a Pricing Proposal is Rejected, the system must preserve:

- the rejected Proposal version;
- rejecting user;
- decision timestamp;
- reason or comment where provided;
- associated approval and workflow history.

Rejection must not delete the Proposal or Pricing Initiative.

Authorised users may subsequently revise the pricing work and create or submit a new Proposal version where appropriate.

The rejected version must remain historically retrievable.

6.17. PROP-017 Material Proposal Change

After formal submission into an organisational decision path, a material change to a Pricing Proposal must not modify the submitted Proposal version in place.

Material changes include changes to relevant:

- pricing scope;
- pricing action;
- proposed price;
- pricing logic;
- consequential assumptions;
- key financial inputs, including the applicable unit cost or cost basis where a change materially alters the pricing outcome, financial analysis, guardrail result, or decision basis;
- decision-relevant change in applicable Guardrail configuration or ANALYSIS-014 evaluation where that change materially alters the Proposal decision basis;
- material exceptions;
- effective pricing action or timing.

Organisational Guardrail configuration remains governed by GOV-023 and GOV-034 and must not be treated as editable Proposal content.

Where a changed organisational Guardrail configuration is explicitly required to become part of the decision basis for already submitted pricing work and that change materially alters the applicable Guardrail evaluation, behavioural treatment or organisational decision basis, the affected pricing work must proceed through a new controlled Proposal version under this requirement.

A later Guardrail configuration change must not silently modify the existing submitted Proposal version or its preserved decision snapshot.

A material change must create a new controlled Proposal version.

The new Proposal version must complete the applicable organisational decision requirements before it can receive execution authority. Depending on the applicable decision path, this may include required review, item-level approval or policy-authorisation evaluation.

Approval or policy authorisation attached to an earlier Proposal version must not transfer to the materially revised Proposal version.

Previous decisions must remain attached to the exact Proposal version against which they were originally made.

Material-change treatment must remain consistent with PROP-019 where the new Proposal version supersedes a previous current version.

6.18. PROP-018 Non-Material Proposal Change

The system may permit limited non-material changes after submission where those changes do not alter the substantive pricing decision.

Examples may include:

- correcting non-consequential descriptive text;
- adding supporting context that does not change the pricing action;
- administrative metadata updates.

Non-material changes must remain attributable and auditable.

A change that affects the commercial meaning, pricing outcome, decision basis or execution instruction must not be treated as non-material.

6.19. PROP-019 Proposal Supersession

When a newer controlled Proposal version replaces a previous version as the current basis for decision or execution, the previous version must be identified as Superseded.

A Superseded Proposal version must:

- remain historically retrievable;
- preserve its original decision history;
- preserve associated approvals, policy authorisations and comments;
- not be represented as the current Proposal version;
- not provide current execution authority where a newer applicable version has replaced it.

Supersession must not delete or rewrite the previous Proposal version.

6.20. PROP-020 Proposal Expiration

A Pricing Proposal may expire where its defined validity period, effective window or applicable organisational validity condition has passed.

An Expired Proposal must not provide current execution authority.

Expiration must preserve:

- the Proposal version;
- its historical decision status;
- previous approvals or policy authorisation;
- expiration timestamp or condition;
- relevant historical context.

Expired pricing work must return through the appropriate decision process before it can become valid execution authority again.

6.21. PROP-021 Decision and Execution Binding

Approval or policy authorisation must bind to the exact controlled Pricing Proposal version against which the decision was made.

An Approved or Authorised Within Policy Proposal version must become the authoritative decision baseline for subsequent execution.

The system must preserve the exact relationship between:

Authorised Proposal Version → Authorised Pricing Action → Execution Record → Actual Implemented Action

Execution, export or implementation must not silently use values from:

- a later Draft;
- a Superseded Proposal version;
- an Expired Proposal version;
- changed workspace data;
- another Scenario;
- another Pricing Initiative.

Any material difference between the authorised Proposal version and actual implementation must remain identifiable as execution variance.

6.22. PROP-022 Proposal Historical Integrity

Every consequential Pricing Proposal must remain historically understandable after the Pricing Initiative progresses or is completed.

For each Proposal version, an authorised user should be able to determine:

- what was proposed;
- which Pricing Initiative it belonged to;
- which pricing scope it affected;
- what baseline or current pricing state was used;
- what pricing action was proposed;
- which assumptions and analysis supported it;
- which guardrails applied;
- which evidence supported the decision;
- who submitted it;
- which version was submitted;

- what decision was made;
- who made the decision;
- whether changes were requested or the Proposal was rejected;
- whether the Proposal was Approved or Authorised Within Policy;
- whether the version later became Superseded or Expired;
- whether it became the basis for execution.

If the exact decision represented by a historical Proposal version cannot be reconstructed from Owómidé, the Proposal record is incomplete.

3.7 Collaboration and Evidence Management

7. COLLABORATION AND EVIDENCE MANAGEMENT

The MVP must allow relevant stakeholders to collaborate directly around pricing work while preserving the relationship between each contribution and the Pricing Initiative, analysis, scenario, proposal or decision it concerns.

Collaboration should reduce off-platform coordination without attempting to replace general workplace communication tools.

7.1. COLLAB-001 Contextual Collaboration

Users must be able to collaborate within a Pricing Initiative.

Collaboration may be attached to:

- the overall initiative;
- pricing scope;
- analysis;
- scenarios;
- pricing logic;
- proposals;
- review activity;
- execution or monitoring records.

Users should be able to understand what object or decision context a contribution refers to.

7.2. COLLAB-002 Comments

Authorised users must be able to add comments to supported pricing objects.

Each comment must preserve:

- author;
- timestamp;
- related pricing object;
- comment content.

Comments must remain part of the historical pricing record.

7.3. COLLAB-003 Threaded Discussion

Where discussion requires follow-up, the MVP should support replies to an existing comment or discussion thread.

Threads must remain associated with the pricing context that initiated them.

The MVP does not need to provide unrestricted organisation-wide chat.

7.4. COLLAB-004 Mentions

Users must be able to mention relevant workspace members in comments or supported collaboration areas.

A mention should:

- identify the mentioned user;
- generate an appropriate notification;
- link the user back to the relevant pricing context.

Mentioning a user must not grant additional data or workflow permissions.

7.5. COLLAB-005 Assignments

Authorised users must be able to assign specific actions to relevant participants.

Assignments may include tasks such as:

- provide cost information;
- review assumptions;
- validate commercial input;
- review a scenario;
- provide supporting evidence;
- complete review;
- implement an authorised pricing action;
- record monitoring information.

Each assignment should contain:

- assigned user;
- action required;

- associated initiative or pricing object;
- status;
- due date where applicable;
- creator;
- creation timestamp.

7.6. COLLAB-006 Assignment Status

Assignments should support at minimum:

- Open;
- In Progress;
- Completed;
- Cancelled.

Completion must remain attributable to the user completing the assignment.

7.7. COLLAB-007 Supporting Evidence

Users must be able to attach Evidence supporting or challenging pricing work.

Evidence is supporting material, observation or externally supplied information used to inform, substantiate or question pricing work. Evidence does not become authoritative structured Pricing Context merely because it is attached to a Pricing Initiative, analysis, Scenario or Pricing Proposal.

Supported Evidence may include:

- uploaded documents;
- spreadsheets or extracts;
- images;
- internal reports;
- external links;
- manually entered observations;
- supplier information;
- competitor observations;
- customer or sales feedback;
- other relevant supporting material.

Evidence must remain attached or referenced to the pricing work it supports.

Evidence may support:

- an Assumption;
- business rationale;
- analytical interpretation;
- a proposed pricing action;
- a review or organisational decision;
- another supported decision-relevant element.

Evidence must remain distinguishable from:

- structured Pricing Context governed by Section 3.2;
- explicit Assumptions;
- deterministic calculations;
- AI-generated interpretation;
- comments or discussion.

Where information originating from Evidence is intentionally converted into structured Owómidé Pricing Context, the resulting structured record must satisfy the applicable Section 3.2 record, validation, provenance and permission requirements.

The source Evidence may remain referenced as provenance, but the Evidence itself must not silently become a Price Record, Cost Record, Current Price, Applicable Unit Cost or another authoritative structured pricing record.

7.8. COLLAB-008 Evidence Metadata

Evidence records should preserve, where available:

- title or description;
- contributor;
- submission date;
- source;
- related pricing object;
- observation date or effective date where relevant.

Users must be able to distinguish evidence from structured system data and AI-generated interpretation.

7.9. COLLAB-009 Manual Market Observations

Because relevant pricing intelligence may originate outside digitised systems, authorised users must be able to record manually gathered market observations.

An observation should support fields such as:

- observation type;
- subject or competitor;
- observed value or price where applicable;
- location;
- channel;
- observation date;
- source or method;
- notes;
- submitting user.

Such observations must not be represented as automatically verified or real-time intelligence.

7.10. COLLAB-010 Evidence Relevance

Users should be able to associate evidence with the specific part of pricing work it informs.

For example, evidence may support:

- an assumption;
- competitor comparison;
- proposed price;
- cost change;
- commercial rationale;
- scenario;
- organisational decision.

This prevents the initiative from becoming an unstructured attachment repository.

7.11. COLLAB-011 Review Feedback

During review, authorised reviewers must be able to provide feedback directly against the pricing work under review.

Review feedback may include:

- comment;
- clarification request;
- identified issue;
- recommended modification;
- readiness confirmation.

Review feedback remains distinct from formal organisational decision authority.

7.12. COLLAB-012 Discussion Resolution

Where appropriate, authorised users should be able to mark a discussion or review issue as resolved.

Resolution must preserve:

- original discussion;
- responses;
- resolving user;
- resolution timestamp.

Resolved discussion must remain available in historical context.

7.13. COLLAB-013 Collaboration Activity

Relevant collaboration events must appear in the Pricing Initiative activity history.

This includes:

- comments;
- replies;
- mentions;
- assignments;
- assignment completion;
- evidence additions;
- review feedback;

- issue resolution.

7.14. COLLAB-014 Access Control

Users may collaborate only on pricing work they are authorised to access.

Collaboration features must respect:

- workspace membership;
- role permissions;
- pricing scope;
- restricted cost visibility;
- sensitive information controls.

A notification, mention or assignment must never expose protected information to an unauthorised user.

7.15. COLLAB-015 Sensitive Evidence

Evidence containing restricted financial or commercial information must be subject to appropriate access restrictions.

The system must not assume that every initiative participant is entitled to view every attached piece of evidence.

7.16. COLLAB-016 Version Context

Where a comment, review note or supporting contribution relates to a controlled proposal or pricing-logic version, the system should preserve the version context.

Users reviewing historical discussion must be able to determine which version was being discussed.

7.17. COLLAB-017 Editing and Deletion

The MVP should protect historical integrity of consequential collaboration.

Where comment editing is allowed:

- the edited state must remain identifiable;
- consequential meaning must not be silently altered after formal decision-making.

Where deletion is permitted, the system should preserve an appropriate audit record rather than allowing historically significant contributions to disappear without trace.

7.18. COLLAB-018 AI in Collaboration

Users may invoke AI to assist with collaborative work.

AI may:

- summarise discussion;
- identify unresolved questions;
- synthesise stakeholder input;
- identify conflicting assumptions;
- prepare a review summary;
- retrieve relevant initiative context.

AI must not attribute a position or decision to a human stakeholder unless that position exists in the recorded collaboration.

7.19. COLLAB-019 Collaboration Summary

The initiative should provide a concise view of relevant outstanding collaboration.

This may include:

- unresolved discussions;
- open assignments;
- outstanding review requests;
- recently added evidence;
- participants awaiting action.

Users should not need to inspect the full activity history to understand what collaborative work remains incomplete.

7.20. COLLAB-020 Collaboration Boundary

The MVP is not required to provide:

- unrestricted direct messaging;
- organisation-wide chat channels;

- voice or video meetings;
- general document editing;
- external social collaboration;
- full project-management functionality.

Collaboration exists to help stakeholders complete pricing work inside a shared decision context.

7.21. COLLAB-021 Collaboration Completeness Principle

For consequential pricing work, Owómidé should preserve enough collaborative context to answer:

Who contributed?
What information or evidence did they provide?
What issues were raised?
What actions were assigned?
What remained unresolved?
What changed because of the collaboration?

The pricing record should remain understandable even after the original participants are no longer available.

3.8 Workflow, Review and Approval Management

8. WORKFLOW, REVIEW AND APPROVAL MANAGEMENT

The MVP must provide a bounded pricing-specific workflow system that governs how Pricing Initiatives and Pricing Proposals move through review, the applicable organisational decision path and execution readiness.

The workflow system must operate within the canonical Pricing Initiative lifecycle defined in Section 2.2.

Organisations may configure supported workflow parameters through a bounded Workflow Configuration Profile, but they must not create arbitrary lifecycle stages, free-form workflow graphs, scripts, unrestricted triggers or general-purpose automation.

Workflow configuration must determine supported organisational workflow behaviour without redefining the canonical Pricing Initiative lifecycle, Pricing Proposal model or Governance authority model.

8.1. FLOW-001 Bounded Workflow Configuration

Authorised administrators must be able to configure supported pricing-specific workflow behaviour through a bounded Workflow Configuration Profile.

A Workflow Configuration Profile may define supported parameters including:

- whether formal review requirements apply within the canonical In Review stage;
- required reviewer roles or participants;
- applicable organisational decision path;
- item-level approval requirements where applicable;
- required approver roles;
- supported sequential or multiple-approval arrangements;
- supported approval-routing conditions;
- target response dates or approval deadlines;
- supported escalation behaviour;
- authorised delegates where organisational policy permits.

Where policy authorisation is enabled, the Workflow Configuration Profile may determine whether eligible pricing work is routed into the policy-authorisation path rather than item-level approval.

Workflow configuration must not independently define policy-authorisation eligibility, authority, qualification thresholds or policy conditions.

Those requirements remain governed by FLOW-022, FLOW-023, GOV-027 and GOV-028.

Workflow Configuration Profiles must operate within the canonical Pricing Initiative lifecycle defined in Section 2.2.

Administrators must not be able to use workflow configuration to:

- create new Pricing Initiative lifecycle states;
- redefine the meaning of canonical lifecycle states;
- create arbitrary state-transition graphs;
- redefine Pricing Proposal status or validity;
- create unrestricted custom workflow stages;
- execute user-authored scripts or code;
- introduce arbitrary executable expressions;
- create arbitrary user-defined triggers or action chains;
- perform general-purpose organisational automation;
- bypass Proposal readiness requirements;
- bypass approval authority;
- bypass maker-checker requirements;
- bypass Guardrails or other Governance controls.

Routing and escalation conditions must use supported pricing-specific condition types exposed by the MVP.

A Workflow Configuration Profile therefore configures supported behaviour inside the Owómidé pricing lifecycle rather than defining a new workflow engine.

8.2. FLOW-002 Default Workflow Configuration

The MVP must provide a system-default Workflow Configuration Profile aligned with the canonical Pricing Initiative lifecycle:

Initiated → In Development → In Review → Awaiting Approval → Ready for Execution → Implemented → Monitoring → Completed

The default configuration must provide a usable pricing workflow without requiring an organisation to build its own workflow structure before performing real pricing work.

Organisations may modify supported workflow parameters defined in FLOW-001.

Configuration must not replace the canonical lifecycle with an alternative lifecycle graph.

Where review, approval routing, policy authorisation, escalation or delegation differs between organisations, those differences must be represented through supported configuration within the canonical lifecycle.

The default Workflow Configuration Profile must remain usable where optional advanced configuration has not been performed.

8.3. FLOW-003 Workflow Configuration Profile Assignment

Each Pricing Initiative must operate under either:

- the system-default Workflow Configuration Profile; or
- another authorised Workflow Configuration Profile supported by the MVP.

The applicable profile may be selected using supported organisational criteria such as:

- initiative type;
- Pricing Scope;
- business unit;
- supported pricing-impact classification;
- applicable organisational policy;
- authorised administrative configuration.

Profile selection must identify an existing supported Workflow Configuration Profile.

The system must not dynamically generate an arbitrary workflow graph for an Initiative from unrestricted user-defined conditions.

The selected Workflow Configuration Profile must remain visible to relevant participants.

The Profile must not alter the canonical Pricing Initiative lifecycle, Proposal statuses, Proposal version-validity states or Governance authority definitions.

8.4. FLOW-004 Review Stage

The applicable Workflow Configuration Profile may require one or more reviewer actions within the canonical In Review stage before a Pricing Proposal progresses through the applicable organisational decision path.

Configuration may determine supported reviewer roles, participants and completion requirements, but it must not create additional Pricing Initiative lifecycle states merely to represent organisation-specific review steps.

A reviewer must be able to:

- inspect the Pricing Proposal and supporting context;
- inspect relevant analysis and assumptions;
- view applicable guardrails;
- comment;
- request clarification;
- confirm review readiness;
- request changes where permitted.

Review completion or readiness confirmation must not by itself make a Pricing Proposal Approved or Authorised Within Policy.

Where a reviewer also possesses the required approval authority, formal approval must still require the separate approval action defined by the applicable approval workflow.

Where the Proposal uses the policy-authorisation path, Authorised Within Policy status may be established only through the configured evaluation defined in FLOW-022 and FLOW-023.

Review activity must therefore remain distinct from the organisational decision authority subsequently established against the Proposal.

8.5. FLOW-005 Review Completion

The system must determine when required review conditions have been satisfied.

Where review is required as part of the applicable organisational decision path, the current controlled Pricing Proposal version must not progress beyond that review stage while mandatory review requirements remain incomplete.

For an item-level approval path, incomplete mandatory review must prevent the Proposal from entering the applicable approval process.

For a policy-authorisation path, incomplete mandatory review must prevent the Proposal from receiving Authorised Within Policy status.

Optional reviews must not block progression unless organisational configuration explicitly requires them.

Review completion must not itself create approval, policy authorisation or execution authority.

8.6. FLOW-006 Proposal Submission into Approval Workflow

An authorised user must be able to submit the current Draft Pricing Proposal version into the applicable approval workflow once the Proposal satisfies the submission-readiness requirements defined in PROP-009.

Submission must use the exact controlled Proposal version and decision snapshot established in accordance with PROP-011.

Upon submission, the workflow system must:

- determine the applicable approval path;
- identify required reviewers or approvers;
- apply relevant routing conditions;
- apply applicable workflow and governance requirements;
- create the required review or approval work items;
- change the Pricing Proposal status from Draft to Awaiting Approval in accordance with PROP-012;
- record the workflow entry, responsible parties and submission event.

The workflow system must not create a separate Pricing Proposal version or independently redefine the contents of the submitted Proposal decision snapshot.

Where the submitted Proposal is materially changed, the resulting treatment must follow PROP-017 and the applicable review and organisational decision process must restart for the new controlled Proposal version.

8.7. FLOW-007 Approval Workflow Entry Readiness

A Pricing Proposal must not enter the approval workflow unless it satisfies the Proposal submission-readiness requirements defined in PROP-009.

Once Proposal readiness has been satisfied, the workflow system must verify that the applicable review and approval process can validly begin.

Workflow-entry blocking conditions may include:

- no applicable workflow being assigned;
- invalid or incomplete workflow configuration;
- required review requirements or reviewer actions that have not been completed;
- required approver roles or authorities that cannot be resolved;
- routing conditions that cannot be evaluated from available information;
- unresolved blocking workflow conditions;
- unresolved blocking governance conditions.

The workflow system must clearly identify any condition preventing the Proposal from entering the approval workflow.

Workflow-entry validation must not independently redefine the Proposal content, analysis, pricing logic or guardrail completeness requirements owned by PROP-009 and their respective functional sections.

8.8. FLOW-008 Approval Routing

The system must determine required approvers using configured organisational workflow and authority rules.

Approval routing must use pricing-specific condition types supported by the MVP.

Administrators must not define arbitrary executable code, scripts, formulas or unrestricted custom expressions for approval routing.

Routing configuration must select and combine supported organisational decision criteria rather than operate as a general rules engine.

Routing may depend on supported decision information such as:

- Proposal type;
- percentage price movement;
- margin impact;
- applicable Pricing Scope;
- Priceable Entity or organisational grouping;

- business unit;
- region;
- channel;
- initiative value or commercial significance;
- other explicitly supported pricing-specific approval-threshold types;
- a GOV-025 Approval Escalation treatment triggered by an applicable ANALYSIS-014 Guardrail Breach.

Where routing depends on Guardrail information, the workflow system must consume the authoritative ANALYSIS-014 evaluation and GOV-025 behavioural treatment.

The workflow system must not independently recalculate the Guardrail result, redefine the Guardrail threshold or assign a different behavioural treatment.

A Warning Guardrail treatment must not by itself create an approval escalation unless another applicable workflow or authority rule independently requires that routing.

An Unable to Evaluate Guardrail state must be handled according to PROP-009 and the applicable organisational decision requirements rather than being silently interpreted as either a pass or a Breach.

Approval routing must not itself grant approval authority.

The selected approver must still possess the required authority and organisational scope.

8.9. FLOW-009 Sequential Approval

The MVP must support sequential approval where one authority must decide before the request moves to another.

For example:

Pricing Manager → Finance Approver → Commercial Approver

The system must preserve the order defined by the organisation.

8.10. FLOW-010 Multiple Required Approvals

Where organisational policy requires more than one approver, the proposal must not become Approved until all required approval conditions are satisfied.

The interface must show:

- required approvers;
- completed approvals;
- outstanding approvals;
- current approval stage.

8.11. FLOW-011 Approval Actions

An authorised approver must be able to perform:

- Approve;
- Reject;
- Request Changes.

Where appropriate, the approver may provide a comment or condition.

Each formal decision must be recorded.

8.12. FLOW-012 Approval Record

Every formal approval decision must preserve:

- approver identity;
- decision;
- timestamp;
- proposal version;
- applicable authority or role;
- comment or condition where provided.

Recorded Approval events must remain immutable historical records and must not be overwritten or deleted.

Where a prior Approval is later withdrawn or otherwise ceases to provide current authority under the applicable workflow or Proposal-validity rules, that change must be recorded as a new attributable event while preserving the original Approval event.

Historical immutability therefore preserves what occurred without implying that an earlier Approval must remain currently operative indefinitely.

8.13. FLOW-013 Maker-Checker Enforcement

A user must not approve a proposal they personally submitted.

This restriction applies at the user identity level even where that user holds multiple roles.

Role stacking must not allow maker-checker controls to be bypassed.

8.14. FLOW-014 Approval Authority

Possessing workspace administrative authority must not automatically grant pricing approval authority.

A user may approve pricing work only where their assigned permissions and scope provide the required commercial authority.

8.15. FLOW-015 Scope-Aware Approval

Approval authority must respect organisational scope.

A user authorised to approve pricing for one:

- business unit;
- product category;
- region;
- channel;
- vendor scope;
- other configured scope

must not automatically receive authority over unrelated pricing work.

8.16. FLOW-016 Approval Binding to Controlled Proposal Version

Every formal approval decision must bind to the exact controlled Pricing Proposal version and decision snapshot submitted into the approval workflow in accordance with PROP-011.

The approval record defined in FLOW-012 must identify the exact Proposal version against which the decision was made.

The workflow system must not:

- apply an approval made against one Proposal version to another Proposal version;
- treat approval of an earlier version as approval of a later revised version;

- allow a mutable Draft Proposal version to receive formal approval;
- reinterpret an approval using pricing context, analysis, assumptions, guardrails or other decision information that changed after submission.

Where a material change creates a new controlled Proposal version under PROP-017, the new version must complete the applicable review and approval requirements independently of approvals recorded against the previous version.

Historical approvals must remain permanently associated with the Proposal version against which they were originally made.

8.17. FLOW-017 Workflow Treatment of Material Proposal Changes

Where a submitted Pricing Proposal is materially changed in accordance with PROP-017, existing approval or policy-authorisation authority must remain applicable only to the Proposal version against which that authority was originally established.

The workflow system must:

- prevent the materially revised pricing action from relying on decision authority attached to the previous Proposal version;
- preserve all reviews, approvals, policy-authorisation records, comments and workflow activity already recorded against the previous version;
- ensure that historical decisions remain bound only to the Proposal version against which they were made;
- require the materially revised pricing work to exist as a new controlled Proposal version;
- determine the applicable organisational decision path for the new Proposal version;
- route the new version through required review and item-level approval where approval is required;
- route the new version through the policy-authorisation evaluation defined in FLOW-022 and FLOW-023 where that path is applicable;
- require the new Proposal version to satisfy its applicable decision requirements before it can become Approved or Authorised Within Policy.

Previous approvals or policy authorisations must not be transferred, inherited or reinterpreted as authority for the materially revised Proposal version.

The workflow treatment of a material change must remain explicit and auditable.

8.18. FLOW-018 Workflow Treatment of Non-Material Proposal Changes

Where a post-submission change is permitted as non-material in accordance with PROP-018, the workflow system may allow the existing review or approval process to continue without requiring a new controlled Proposal version.

The change must not alter the substantive decision snapshot established under PROP-011 or change the commercial meaning of the Proposal being reviewed.

The workflow system must:

- preserve the exact submitted Proposal version against which existing reviews and approvals apply;
- record the non-material change, responsible user and timestamp;
- make the change visible to relevant reviewers or approvers where appropriate;
- preserve the relationship between the change and the affected Proposal version;
- prevent a change classified as non-material from modifying pricing scope, pricing action, pricing outcome, decision basis or execution instructions.

Where a change exceeds the non-material boundary defined in PROP-018, it must instead be treated as a material Proposal change under PROP-017 and FLOW-017.

Non-material changes must remain attributable and auditable throughout the applicable organisational decision process.

8.19. FLOW-019 Workflow Treatment of Changes Requested

When an authorised reviewer or approver records Changes Requested against the current controlled Pricing Proposal version, the workflow system must:

- change the applicable Proposal status to Changes Requested in accordance with PROP-012 and PROP-015;
- stop that Proposal version from continuing through the active approval path;
- preserve the requesting user, timestamp, request or comment and associated workflow activity;
- keep the request attached to the exact Proposal version against which it was made;
- return the Pricing Initiative to the appropriate In Development or In Review stage according to the applicable workflow;
- make the required revision or next action visible to responsible users.

Where the requested change results in a material Proposal change, the revised pricing work must become a new controlled Proposal version in accordance with PROP-017 before it can be resubmitted.

Reviews or approvals recorded against the previous Proposal version must not automatically transfer to the revised version.

A Proposal with Changes Requested must not progress to Ready for Execution unless a subsequently applicable Proposal version becomes Approved or Authorised Within Policy.

8.20. FLOW-020 Workflow Treatment of Rejection

When an authorised approver Rejects the current controlled Pricing Proposal version, the workflow system must:

- record the rejection against the exact Proposal version;
- change the applicable Proposal status to Rejected in accordance with PROP-012 and PROP-016;
- stop the active approval path for that Proposal version;
- preserve all completed reviews, approval actions, comments and workflow history associated with the rejected version;
- prevent the rejected Proposal version from progressing to execution;
- make the rejection and required next organisational action visible to relevant users.

Rejection of a Pricing Proposal must not automatically cancel or delete the Pricing Initiative.

Where authorised users continue the Initiative after rejection, subsequent revised pricing work must proceed through the applicable Proposal creation, versioning, review and organisational decision requirements before execution authority can be established.

The rejected Proposal version must remain permanently associated with its historical workflow and decision record.

8.21. FLOW-021 Approval Completion and Execution Readiness

A Pricing Proposal becomes Approved only when all required approval conditions for the current controlled Proposal version have been satisfied.

While required approvals remain outstanding, the Proposal must remain Awaiting Approval. Partial completion of an approval chain must be represented as approval progress, not as a separate Pricing Proposal status.

Rejected and Changes Requested must be represented using the Pricing Proposal statuses defined in PROP-012.

Expiration must be represented through Pricing Proposal version validity as defined in PROP-013, not as an approval state or Pricing Proposal decision status.

A Pricing Initiative may progress to Ready for Execution only when its current applicable Pricing Proposal is Approved or validly Authorised Within Policy, the applicable Proposal version remains valid for execution, and all other applicable execution conditions are satisfied.

8.22. FLOW-022 Policy Authorisation Path

An organisation may optionally configure a policy-authorisation path under which an eligible current Draft Pricing Proposal version may receive Authorised Within Policy status without item-level human approval.

This capability must remain disabled unless deliberately configured by an authorised organisational user.

The policy-authorisation path must operate against the exact controlled Proposal version and decision snapshot submitted into that path in accordance with PROP-003 and PROP-011.

Policy evaluation must identify, where applicable:

- exact Pricing Proposal version;
- applicable organisational policy;
- qualifying policy conditions;
- authorised Pricing Scope;
- submitting or invoking user and applicable authority;
- applicable Guardrail identifiers and configuration versions preserved under PROP-011;
- applicable ANALYSIS-014 Guardrail evaluation results;
- applicable GOV-025 Guardrail behavioural treatments;
- policy-evaluation result;

- evaluation timestamp.

The policy-authorisation path must consume the Guardrail configuration and evaluation preserved with the controlled Proposal decision snapshot.

It must not independently recalculate a Guardrail result or replace the preserved Guardrail configuration with a later governance configuration.

Policy-authorisation rules may require particular Guardrail states or behavioural conditions, but they must not redefine the Guardrail itself or the deterministic method used to evaluate it.

Where all applicable policy-authorisation requirements are satisfied, the exact controlled Proposal version may receive Authorised Within Policy status in accordance with PROP-012.

Policy authorisation must bind only to that exact controlled Proposal version in accordance with PROP-021.

A later Proposal version, materially revised pricing action or other Pricing Initiative must not inherit that policy authorisation.

Failure and blocking treatment must follow FLOW-023.

8.23. FLOW-023 Policy Authorisation Boundary

A Pricing Proposal version must not receive Authorised Within Policy status where any applicable policy-authorisation condition is unsatisfied.

Blocking conditions must include, where applicable:

- the Proposal does not satisfy PROP-009 decision-readiness requirements;
- the Proposal version is not the Current applicable version;
- required decision information is missing;
- an applicable Guardrail has an ANALYSIS-014 evaluation state of Breach and a GOV-025 behavioural treatment of Blocking;
- a required Guardrail is Unable to Evaluate and the applicable policy does not explicitly permit progression without that evaluation;
- an applicable Guardrail Breach has Approval Escalation treatment and the resulting organisational decision path requires item-level or higher human approval;
- the initiating or submitting user lacks required authority;

- the pricing action exceeds configured policy-authorisation thresholds;
- the Proposal falls outside authorised Pricing Scope;
- the Proposal cannot be reliably evaluated against the configured policy;
- an applicable workflow or governance rule requires explicit item-level approval.

A Warning Guardrail treatment must not by itself be treated as a Blocking Guardrail condition.

The policy-authorisation evaluation must consume the Guardrail information preserved with the exact controlled Proposal version under PROP-011.

It must not independently calculate another Guardrail result or reinterpret the Proposal using a later Guardrail configuration.

Failure of policy authorisation must not create execution authority or cause the Proposal to be represented as Authorised Within Policy.

Where item-level approval is required, the Proposal must instead enter the applicable approval workflow and follow the approval requirements in this section.

A failed policy-authorisation evaluation must remain attributable and auditable where it materially affects Proposal progression.

8.24. FLOW-024 Urgent Workflow

Authorised users must be able to mark qualifying pricing work as urgent.

Urgent status may trigger:

- priority notification;
- shorter response expectations;
- escalation;
- alternate authorised approvers where configured;
- prominent work-queue placement.

Urgency must not bypass required review, item-level approval, policy-authorisation conditions, maker-checker controls, guardrails or other applicable governance requirements.

8.25. FLOW-025 Approval Deadlines

Workflows should support target response dates or approval deadlines where appropriate.

Relevant users must be able to see when an approval is:

- pending;
- approaching deadline;
- overdue.

8.26. FLOW-026 Escalation

The MVP should support bounded escalation rules for overdue pricing work.

Escalation configuration must be limited to supported trigger parameters and supported escalation actions defined by the MVP.

Escalation must not execute arbitrary user-defined actions, modify Pricing Proposal content, change the controlled decision snapshot, create approval authority or act as a general-purpose automation mechanism.

Escalation may:

- notify the current approver;
- notify an authorised manager;
- route to an alternate authorised approver where configured.

Escalation must never grant approval authority to an otherwise unauthorised user.

8.27. FLOW-027 Approval Delegation

Where organisational policy permits, an approver may have an authorised delegate.

Delegation must be:

- explicitly configured;
- time-bounded where appropriate;
- scope-aware;
- auditable.

Delegation must not weaken maker-checker restrictions.

8.28. FLOW-028 Approval Withdrawal

An approval may be withdrawn only where organisational policy permits and before execution has made the decision operationally irreversible.

Withdrawal must preserve:

- original approval;
- withdrawing user;
- timestamp;
- reason;
- resulting workflow state.

The historical approval record must not be deleted.

8.29. FLOW-029 Workflow Treatment of Expiration

Pricing Proposal expiration must be represented through Proposal version validity in accordance with PROP-013 and PROP-020.

Where an expiration condition causes the current Proposal version to lose validity for progression or execution, the workflow system must:

- prevent that Proposal version from progressing to Ready for Execution or further execution;
- preserve the historical Proposal status and all previous review, Approval and Policy Authorisation records;
- identify the Proposal version as Expired through the canonical Proposal validity model;
- stop or close outstanding workflow actions that no longer remain valid;
- make the expiration condition and required next action visible to relevant users.

Where organisational policy causes an Approval or Policy Authorisation to cease providing current execution authority, the system must preserve the original decision record as historical evidence while preventing it from continuing to provide current execution authority.

Pricing work that has expired must return through the applicable Proposal and decision process before new execution authority can be established.

Expiration must not delete, rewrite or reinterpret the historical decision originally made against the Proposal version.

8.30. FLOW-030 Execution Readiness Gate

The workflow system must prevent a Pricing Initiative from entering Ready for Execution unless:

- the current applicable Pricing Proposal status is Approved or Authorised Within Policy;
- the applicable Proposal version remains Current and valid for execution in accordance with PROP-013 and PROP-020;
- the exact authorised Proposal version is identifiable as the execution baseline defined in PROP-021;
- all required approval or policy-authorisation conditions have been satisfied;
- no blocking workflow condition remains;
- no blocking governance condition remains;
- no unresolved condition invalidates execution readiness.

A Superseded, Expired, Rejected, Changes Requested, Awaiting Approval or Draft Proposal version must not provide execution authority.

When the Pricing Initiative progresses to Ready for Execution, the Pricing Proposal must retain its existing Approved or Authorised Within Policy status.

Progression of the Pricing Initiative must not modify, replace or reinterpret the authorised Proposal version or its decision snapshot.

The exact Proposal version that passes the execution-readiness gate must remain the authoritative baseline for subsequent execution, export and implementation comparison.

Execution-readiness validation must consume the exact authorised Proposal version and controlled decision snapshot, including the Guardrail configuration and evaluation preserved under PROP-011.

The execution-readiness gate must not independently recalculate Guardrails using later workspace values or substitute a newer Guardrail configuration solely because organisational governance has changed after the Proposal decision.

Where a later governance or Guardrail configuration change is explicitly required to affect active pricing work, the resulting treatment must follow GOV-034 and the applicable Proposal and workflow requirements before the authoritative execution baseline can change.

The workflow system must not silently reinterpret an Approved or Authorised Within Policy Proposal using governance information that was not part of its controlled decision basis.

8.31. FLOW-031 Workflow Visibility

Relevant users must be able to understand:

- current workflow state;
- completed stages;
- outstanding stages;
- current responsible party;
- required next action;
- pending approvals;
- blocking issues.

The workflow state must not depend on users reconstructing status from comments or activity logs.

8.32. FLOW-032 Workflow Notifications

Relevant workflow events must trigger notifications where appropriate, including:

- review request;
- approval request;
- changes requested;
- rejection;
- approval;
- policy authorisation;
- escalation;
- execution readiness.

Notifications must link users back to the relevant Pricing Initiative and proposal context.

8.33. FLOW-033 Workflow Audit History

Every consequential workflow event must be preserved in chronological history.

This includes:

- submission;

- routing;
- review completion;
- approval;
- rejection;
- changes requested;
- escalation;
- delegation;
- expiration;
- re-submission;
- policy authorisation;
- execution readiness.

8.34. FLOW-034 Historical Authority Context

Historical pricing records must preserve the organisational authority and decision-path context under which consequential decisions occurred.

Relevant historical context must include, where applicable:

- user roles and permissions;
- organisational scope;
- approval authority and limits;
- policy-authorisation configuration and qualification conditions;
- applicable workflow configuration;
- decision path used;
- relevant governance restrictions;
- user membership and identity state.

Subsequent changes to any of these conditions must not rewrite the authority context of previously completed pricing decisions.

Historical records must remain sufficient to determine why a Pricing Proposal was permitted to become Approved or Authorised Within Policy under the conditions that existed at that time.

8.35. FLOW-035 Workflow Configuration Changes

Consequential changes to a Workflow Configuration Profile must apply prospectively according to defined system behaviour.

Each consequential Workflow Configuration Profile state must remain historically distinguishable.

The system must preserve, where applicable:

- Workflow Configuration Profile identifier;
- configuration version or revision;
- previous configuration state;
- resulting configuration state;
- responsible user;
- change timestamp;
- effective date or effective period where relevant.

A submitted controlled Pricing Proposal version must remain associated with the exact organisational decision path and applicable Workflow Configuration Profile state that formed part of its controlled decision context.

Subsequent Workflow Configuration Profile changes must not silently alter the:

- required review requirements or reviewer actions;
- item-level approval requirements;
- approval sequence;
- policy-authorisation routing treatment;
- approval-routing conditions;
- deadline or escalation treatment;
- authorised-delegation treatment;
- other consequential decision requirements

applicable to an already submitted Proposal version.

A Workflow Configuration Profile change must not create new Pricing Initiative lifecycle states, redefine canonical lifecycle meaning, redefine Pricing Proposal statuses or validity, or introduce capabilities excluded by FLOW-001 and Section 2.4.

Where a changed Workflow Configuration Profile must affect active pricing work, that treatment must be explicit, attributable and auditable and must follow the applicable Proposal-version and workflow requirements before the active decision path changes.

Historical Proposal versions must continue to preserve the exact workflow configuration and organisational decision context that applied at the relevant time.

8.36. FLOW-036 Workflow Integrity Principle

For every consequential Pricing Proposal decision, the MVP must be able to determine:

- who submitted the Proposal;
- which exact controlled Proposal version was submitted;
- which organisational decision path applied;
- which workflow and governance rules applied;
- who reviewed it where review was required;
- who approved, rejected or requested changes where item-level approval applied;
- which policy and qualification conditions produced Authorised Within Policy where policy authorisation applied;
- under what authority the decision occurred;
- what materially changed after submission or review;
- which exact Proposal version ultimately provided execution authority;
- whether the actual implementation matched that authorised decision baseline.

Approval and policy authorisation must remain distinguishable historical decision paths.

If these questions cannot be answered from the system record, the workflow is not sufficiently controlled.

3.9 Roles, Permissions and Pricing Governance

9. ROLES, PERMISSIONS AND PRICING GOVERNANCE

The MVP must enforce pricing authority through system-level permissions rather than relying on organisational convention or user discretion.

A user's effective authority must be determined by:

Role × Action × Resource × Scope

Possessing access to a Pricing Initiative does not automatically grant authority to perform every action within it.

9.1. GOV-001 Role-Based Access Control

The MVP must support configurable role-based access control.

A role defines the categories of actions a user may perform.

Permissions must be enforced server-side for protected actions and data.

9.2. GOV-002 Core MVP Roles

The MVP should support the following core roles:

- Account Owner;
- Workspace Admin;
- Pricing Manager;
- Pricing Analyst;
- Pricing Contributor;
- Finance Approver;
- Commercial Approver;
- Executive Approver;
- Executor;
- Viewer;
- Auditor.

Additional specialised roles may be configured using supported permission combinations where necessary.

9.3. GOV-003 Account Owner

The Account Owner has top-level responsibility for organisation membership and administrative continuity.

The Account Owner may manage:

- workspace ownership;
- administrators;
- organisation settings;
- membership.

Account ownership must not automatically grant pricing approval or execution authority.

9.4. GOV-004 Workspace Admin

A Workspace Admin may manage supported workspace configuration including:

- users;
- roles;
- access scopes;
- workflow configuration;
- pricing policies;
- guardrails;
- organisational settings.

Administrative authority must remain distinct from commercial pricing authority.

9.5. GOV-005 Pricing Manager

A Pricing Manager may, within authorised scope:

- create and manage Pricing Initiatives;
- construct pricing work;
- manage collaborators;
- review pricing analysis;
- create Pricing Proposals;
- submit proposals;

- coordinate pricing workflows.

Approval authority must be separately granted where required.

9.6. GOV-006 Pricing Analyst

A Pricing Analyst may, within authorised scope:

- access relevant pricing context;
- perform pricing analysis;
- create scenarios;
- contribute to Pricing Builder work;
- prepare pricing recommendations;
- collaborate on initiatives.

An analyst must not automatically receive formal approval authority.

9.7. GOV-007 Pricing Contributor

A Pricing Contributor may participate in defined portions of pricing work according to assigned permissions.

This may include:

- providing context;
- commenting;
- uploading evidence;
- completing assignments;
- contributing defined pricing inputs.

9.8. GOV-008 Finance Approver

A Finance Approver may formally approve pricing work where financial approval is required and the proposal falls within their authorised scope and authority level.

Finance approval may consider:

- cost;
- margin;
- profitability;

- financial guardrails;
- related financial implications.

9.9. GOV-009 Commercial Approver

A Commercial Approver may formally approve pricing work where commercial authority is required.

Commercial approval may consider:

- market positioning;
- customer impact;
- revenue implications;
- commercial strategy;
- channel or category considerations.

9.10. GOV-010 Executive Approver

An Executive Approver may approve proposals requiring higher organisational authority.

Executive approval must still respect defined scope and approval rules.

Holding an executive role must not automatically override system governance.

9.11. GOV-011 Executor

An Executor may carry out, coordinate or record authorised pricing actions within their permitted execution scope.

Execution authority must apply only to pricing actions supported by a valid controlled Pricing Proposal version with current execution authority.

Execution authority does not itself grant authority to:

- modify the authorised Pricing Proposal version;
- change the authorised pricing action or scope;
- create an approval;
- create policy authorisation;
- bypass applicable organisational decision requirements;

- alter the controlled decision snapshot;
- alter the historical decision record.

An Executor must not treat access to an executable pricing action as authority to redefine the decision that produced it.

Actual implementation must remain attributable to the applicable authorised Proposal version and Execution Record.

9.12. GOV-012 Viewer

A Viewer may inspect permitted pricing information without modifying consequential pricing work.

Viewer access must respect sensitive-data restrictions and assigned organisational scope.

9.13. GOV-013 Auditor

An Auditor may inspect relevant historical pricing records, including where authorised:

- proposals;
- versions;
- approvals;
- policy-authorisation records;
- workflow history;
- execution history;
- administrative changes;
- audit records.

Audit access is read-only unless additional permissions are explicitly granted.

9.14. GOV-014 Multiple Roles

A user may hold multiple roles where required by the organisation.

Effective permissions may combine authorised capabilities from those roles.

Role stacking must not override identity-level restrictions such as maker-checker separation.

9.15. GOV-015 Permission Categories

The permission system must distinguish actions such as:

- View;
- Create;
- Edit;
- Analyse;
- Comment;
- Assign;
- Review;
- Submit;
- Approve;
- Reject;
- Request Changes;
- Execute;
- Configure;
- Export;
- Audit.

Permissions must be evaluated against the relevant resource and scope.

9.16. GOV-016 Resource-Level Permissions

Permissions must apply to defined resource types such as:

- organisation settings;
- users;
- pricing data;
- costs;
- Pricing Initiatives;
- Pricing Builder logic;
- scenarios;
- Pricing Proposals;
- approvals;
- policy-authorisation records;
- execution records;
- monitoring information;
- audit history.

A user may therefore have different authority across different product objects.

9.17. GOV-017 Scope-Based Authority

Permissions must support limiting authority by organisational scope.

Relevant scopes may include:

- business unit;
- category;
- product group;
- product;
- region;
- location;
- channel;
- customer group;
- vendor;
- price list.

A user authorised for one scope must not automatically gain authority outside that scope.

9.18. GOV-018 Effective Permission Evaluation

For every protected action, the system must determine:

1. whether the user is an active organisation member;
2. whether their role permits the action;
3. whether they may act on the relevant resource;
4. whether the resource falls within their permitted scope;
5. whether additional governance restrictions apply.

Failure of any required condition must prevent the action.

9.19. GOV-019 Maker-Checker Separation

A user who submits a Pricing Proposal must not approve that same submitted proposal.

This restriction applies to the individual user identity.

It must remain enforced even where the user:

- holds multiple roles;
- is a Workspace Admin;
- is an Account Owner;
- possesses approval permissions through another role.

9.20. GOV-020 Commercial Authority Separation

The system must distinguish operational participation from commercial authority.

The ability to:

- create;
- analyse;
- review;
- administer;
- execute

must not automatically grant approval authority.

Approval authority must be explicit.

9.21. GOV-021 Cost Visibility

Access to sensitive cost information must be independently controllable.

A user may participate in pricing work without necessarily being permitted to view cost data.

Cost visibility controls must apply across:

- product records;
- initiative context;
- analysis;
- scenarios;
- proposals;
- exports;
- AI interactions.

9.22. GOV-022 Protection Against Derived Cost Disclosure

Where cost visibility is restricted, the system must also prevent disclosure through directly derivable financial outputs where those outputs would effectively reveal the restricted cost.

The permission model must therefore consider both raw values and sensitive derived information.

9.23. GOV-023 Guardrail Definition and Management Authority

Only authorised administrative or policy-management users may create, modify, activate or deactivate organisational pricing guardrails.

A Guardrail is a configured organisational pricing constraint used to evaluate whether proposed pricing work remains within an acceptable pricing boundary.

A Guardrail must remain distinct from:

- approval authority;
- approval-routing thresholds;
- workflow-routing rules;
- policy-authorisation eligibility;
- user permissions;
- initiative-specific assumptions or commercial targets.

Supported organisational guardrails for the MVP may include, where applicable:

- minimum gross-margin threshold;
- maximum discount;
- maximum price increase;
- maximum price decrease;
- maximum absolute or percentage price movement;
- another supported pricing constraint that can be evaluated from structured pricing information.

Each configured Guardrail must identify, where applicable:

- persistent Guardrail identifier;
- name or human-readable description;
- guardrail type;
- metric or pricing condition being evaluated;
- operator or comparison rule;
- threshold or configured value;
- applicable organisational or Pricing Scope;
- applicable pricing dimensions where relevant;

- behavioural treatment;
- effective date or effective period where relevant;
- active or inactive status.

Supported behavioural treatment must follow GOV-025.

A Guardrail may apply organisation-wide or to a supported organisational or pricing scope.

Where more than one Guardrail applies to the same pricing work, each applicable Guardrail must remain separately identifiable and evaluable.

Guardrail configuration must not itself determine whether a Pricing Proposal is Approved, Rejected or Authorised Within Policy.

Approval authority, approval-routing thresholds and policy-authorisation qualification remain governed by their respective workflow and governance requirements.

The system must preserve enough configuration information for the analytical layer to evaluate applicable Guardrails deterministically where the required pricing inputs are available.

Where a Guardrail cannot be deterministically evaluated from supported structured information, the product must not invent a result or treat the Guardrail as satisfied.

Consequential Guardrail configuration changes must be attributable, auditable and historically traceable in accordance with GOV-034.

Changes to a Guardrail must apply prospectively according to the applicable governance and Proposal-version rules and must not silently reinterpret the Guardrail configuration preserved with an already submitted Pricing Proposal version.

9.24. GOV-024 Guardrail Enforcement and Ownership Boundary

Applicable organisational Guardrails must be enforced consistently wherever consequential pricing work is performed.

Governance must determine:

- which configured Guardrails apply to the pricing work;
- which Guardrail configuration version applies;
- the applicable scope and pricing dimensions;

- the behavioural treatment configured under GOV-025.

Deterministic evaluation of an applicable Guardrail against pricing values or calculated outcomes must be performed by the analytical layer in accordance with ANALYSIS-014.

Governance must consume the resulting analytical Guardrail evaluation rather than independently calculating a second Guardrail result.

The same applicable Guardrail configuration and evaluation result must be consumed consistently by:

- Pricing Builder;
- analysis and Scenarios;
- Proposal readiness and submission;
- review;
- item-level approval routing where relevant;
- policy-authorisation evaluation;
- execution readiness;
- historical reconstruction.

A user must not be able to obtain a different Guardrail outcome merely by moving pricing work between product surfaces.

Where decision-relevant pricing inputs change while the work remains editable, applicable Guardrail evaluations must be refreshed using the analytical layer.

Where a Pricing Proposal has already been submitted, subsequent Guardrail configuration changes must not silently replace or reinterpret the Guardrail configuration and evaluation preserved with that controlled Proposal version.

Guardrail definition, applicability and behavioural treatment remain governed by Section 3.9.

Guardrail calculation and evaluation remain governed by Section 3.5.

9.25. GOV-025 Guardrail Behavioural Treatment

Each configured Guardrail must have a supported behavioural treatment that determines the governance consequence of a confirmed Guardrail Breach.

Supported MVP treatments must include:

Warning

A confirmed Breach may continue through the pricing process where other applicable requirements are satisfied, but the Breach must remain prominently visible to relevant users and within the decision record.

Approval Escalation

A confirmed Breach requires the pricing work to follow the configured higher or additional approval path before organisational decision authority can be established.

Approval Escalation must not itself grant approval authority or determine which user may approve the pricing work.

Applicable approval authority and routing remain governed by the workflow and approval requirements.

Blocking

A confirmed Breach prevents the affected pricing work from progressing beyond the applicable controlled gate until:

- the pricing work is changed so that the Guardrail is no longer breached; or
- an explicitly supported governance path permits progression under organisational policy.

A Guardrail evaluation state of Within Guardrail must not trigger an adverse Guardrail treatment.

Unable to Evaluate must remain distinct from a confirmed Breach.

Where a Guardrail is required for a consequential decision and its evaluation state is Unable to Evaluate, the system must not treat the Guardrail as satisfied.

The applicable Proposal, workflow or policy-authorisation requirement must determine whether pricing work with an Unable to Evaluate result may progress.

Guardrail behavioural treatment must be configured through governance and must not be redefined independently by the Pricing Builder, analytical layer, workflow or AI.

9.26. GOV-026 Approval Authority Levels

Where required, the organisation must be able to define approval authority according to supported thresholds.

Authority may depend on factors such as:

- magnitude of price change;
- margin level;
- discount level;
- category;
- business unit;
- commercial significance;
- geographic or channel scope.

A user must not approve work exceeding their configured authority.

9.27. GOV-027 Policy Authorisation Configuration

The governance system must support organisational configuration of the Authorised Within Policy decision path defined in FLOW-022.

This capability must be disabled by default.

Only users with appropriate administrative or policy-management authority may enable or modify the policy-authorisation configuration.

Supported configuration may define, where applicable:

- eligible organisational pricing policies;
- authorised pricing scopes;
- applicable thresholds or limits;
- roles or users permitted to submit pricing work into the policy-authorisation path;
- required Guardrails and, where applicable, required Guardrail evaluation states or behavioural treatments;
- applicable policy conditions;
- circumstances requiring item-level approval instead.

Policy-authorisation configuration may reference organisational Guardrails and may specify required Guardrail evaluation states or behavioural treatments as qualification conditions.

It must not independently define or modify the referenced Guardrail, calculate the Guardrail result or redefine its behavioural treatment.

Guardrail definition and applicability remain governed by GOV-023.

Deterministic Guardrail evaluation remains governed by ANALYSIS-014.

Guardrail behavioural treatment remains governed by GOV-025.

Enabling or configuring the policy-authorisation capability must not itself authorise any Pricing Proposal.

Consequential changes to policy-authorisation configuration must be attributable, auditable and historically preserved in accordance with GOV-034.

A Pricing Proposal may receive Authorised Within Policy status only through evaluation of the exact controlled Proposal version under the applicable workflow and governance rules.

9.28. GOV-028 Policy Authorisation Governance Enforcement

When a Pricing Proposal enters the policy-authorisation path, the governance system must enforce the organisational authority and configuration applicable to that decision path.

Governance evaluation must verify, where applicable:

- that the policy-authorisation capability is enabled;
- that the applicable policy exists and is currently valid;
- that the submitting or invoking user possesses the required authority;
- that the Pricing Proposal falls within the user's permitted organisational and pricing scope;
- that the applicable policy and guardrail configuration may be applied to the Proposal;
- that no permission or governance restriction requires the action to be rejected from the policy-authorisation path.

Where Guardrails form part of policy-authorisation qualification, governance evaluation must consume:

- applicable Guardrail identifiers;
- applicable Guardrail configuration versions;
- applicable GOV-025 behavioural treatments;

- authoritative ANALYSIS-014 evaluation results preserved with the exact controlled Proposal decision snapshot under PROP-011.

GOV-028 must not perform a separate quantitative Guardrail calculation or substitute a later Guardrail configuration for the configuration preserved with the submitted Proposal version.

A policy condition may require a particular Guardrail evaluation state or behavioural treatment, but the Guardrail definition, deterministic evaluation, and behavioural treatment must remain owned by their canonical functional requirements.

A user must not be able to obtain policy authorisation by modifying their own role, scope, authority or policy eligibility through the Pricing Proposal.

Failure of a governance condition must prevent the Proposal from receiving Authorised Within Policy status.

Routing and decision treatment following a failed policy-authorisation evaluation must follow FLOW-023.

This requirement governs authority and policy configuration. It must not independently redefine Proposal readiness, Proposal status or the substantive policy-qualification rules owned by their respective functional requirements.

9.29. GOV-029 No Implicit Privilege Escalation

Actions performed inside one Pricing Initiative must not grant additional organisation-level authority.

Being:

- assigned;
- mentioned;
- invited to collaborate;
- made initiative owner

must not expand the user's underlying permissions.

9.30. GOV-030 AI Permission Inheritance

AI must operate using the permission context of the user invoking it.

AI must not access or reveal:

- resources outside the user's scope;
- restricted cost information;
- pricing initiatives the user cannot access;
- protected historical records;
- unavailable organisational information.

9.31. GOV-031 AI Authority Boundary

AI must not possess independent organisational authority.

AI cannot:

- submit proposals autonomously;
- formally approve;
- reject;
- authorise;
- execute pricing actions;
- modify governance configuration;
- grant permissions.

AI must not independently perform consequential governed actions. Formal item-level Approval decisions require authorised human action. Policy Authorisation may establish organisational decision authority only through the non-AI, configured governance mechanism defined in FLOW-022, GOV-027 and GOV-028.

9.32. GOV-032 Permission Change Behaviour

When a user's role, scope or permission changes, future access must reflect the new configuration.

Historical records must continue to preserve the authority and identity context that existed when previous actions were performed.

9.33. GOV-033 User Suspension and Revocation

Suspending or deactivating a user must immediately prevent new protected actions.

Existing:

- comments;
- analyses;
- submissions;
- approvals;
- policy-authorisation records;
- execution records;
- audit events

must remain preserved.

9.34. GOV-034 Governance Configuration Versioning and Historical Context

Consequential governance configuration must remain historically traceable.

The system must preserve consequential changes to supported governance configuration including:

- roles;
- permissions;
- approval authority and limits;
- Guardrails;
- workflow policies;
- scope assignments;
- policy-authorisation configuration and conditions.

For each consequential governance configuration change, the system must preserve, where applicable:

- affected configuration object;
- persistent configuration identifier;
- configuration version or revision;
- previous configuration state;
- resulting configuration state;
- responsible user;
- change timestamp;
- effective date or effective period where relevant.

For Guardrails specifically, each consequential configuration state must remain identifiable through the persistent Guardrail identifier and the applicable configuration version or revision.

A change to a Guardrail threshold, operator, applicable scope, behavioural treatment, effective period or active status must create historically distinguishable governance configuration.

Submitted Pricing Proposal versions must remain associated with the exact governance and Guardrail configuration that formed part of their controlled decision snapshot.

A later governance configuration change must not silently rewrite:

- an earlier Proposal decision snapshot;
- the Guardrail evaluation preserved with that Proposal;
- a historical approval or policy authorisation;
- the governance context under which an earlier decision occurred.

Where a changed governance configuration must affect active pricing work, the resulting treatment must be explicit, attributable and auditable and must follow the applicable Proposal, workflow and governance requirements.

Historical pricing decisions must remain sufficient to determine which governance configuration applied at the relevant time.

9.35. GOV-035 Permission Failure Behaviour

Where a user attempts an unauthorised action, the system must:

- prevent the action;
- avoid exposing restricted data;
- communicate that the action is not permitted.

The system must not rely solely on hiding interface controls as the security mechanism.

9.36. GOV-036 Governance Audit Trail

Consequential governance actions must be recorded with:

- actor;
- action;

- affected user or configuration;
- timestamp;
- previous state where relevant;
- resulting state.

9.37. GOV-037 Governance Integrity Principle

For any consequential pricing action, Owómidé must be able to determine:

Who performed the action?
What role and authority did they possess?
What resource were they acting on?
Was that resource inside their permitted scope?
Which guardrails applied?
Was separation of duties respected?
What governance configuration existed at that time?

If the system cannot answer these questions reliably, the pricing action is not sufficiently governed.

3.10 AI Assistance and AI Governance

10. AI ASSISTANCE AND AI GOVERNANCE

AI is a cross-cutting capability of the Owómidé MVP.

It must assist users inside the pricing workflow rather than operate as a separate chatbot detached from pricing context.

AI may help users interpret, construct, analyse and navigate pricing work, but authoritative pricing data, deterministic calculations, governance decisions and consequential actions must remain controlled by the product and authorised human users.

10.1. AI-001 Contextual AI Assistance

AI assistance must be available within relevant pricing contexts, including:

- Pricing Initiatives;
- Pricing Builder;
- analysis and scenarios;
- proposals;
- review;
- collaboration;
- historical pricing work.

The AI should inherit the context of the object from which it is invoked.

10.2. AI-002 User-Initiated AI

AI assistance in the MVP must be user-invoked for consequential pricing work.

AI must not independently:

- modify pricing logic;
- change proposals;
- submit work;
- approve work;
- execute pricing actions;
- alter governance configuration.

AI may surface passive warnings or suggestions where supported, but consequential changes require explicit human action.

10.3. AI-003 Permission Inheritance

AI must operate within the permissions of the user invoking it.

The AI must not access, infer or expose information the user is not authorised to view.

This includes restrictions relating to:

- initiatives;
- organisational scope;
- cost information;
- sensitive financial information;
- historical pricing records;
- governance configuration.

10.4. AI-004 Cost Visibility Enforcement

Where a user does not have permission to view cost information, AI must not disclose:

- raw costs;
- restricted unit economics;
- directly derivable cost values;
- summaries that reveal protected cost information.

AI access must not become a mechanism for circumventing workspace permissions.

10.5. AI-005 Pricing Context Interpretation

Users must be able to ask AI to help interpret available pricing context.

AI may assist with:

- summarising the pricing situation;
- explaining relevant historical context;
- identifying important available inputs;
- highlighting missing information;
- identifying conflicting information;

- explaining the relationship between pricing inputs and the current initiative.

10.6. AI-006 Pricing Work Construction

AI may assist users in developing pricing work.

This includes:

- drafting pricing strategies;
- converting business intent into structured pricing logic;
- drafting rules and conditions;
- suggesting parameters;
- identifying required assumptions;
- refining rationale;
- helping structure a Pricing Proposal.

AI-created material remains proposed content until explicitly applied by an authorised user.

10.7. AI-007 Natural Language to Structured Pricing Logic

Users should be able to describe pricing intent in natural language and request AI assistance in translating it into supported Pricing Builder structures.

For example:

"Increase prices for these products by 5%, but do not allow gross margin to fall below 18%."

AI may translate this into structured:

- pricing action;
- affected scope;
- percentage adjustment;
- initiative-specific margin constraint or reference to an applicable organisational Guardrail;
- applicable conditions.

Natural-language pricing intent must not cause AI to create or modify an organisational Guardrail through ordinary Pricing Builder work.

Where the user's instruction describes a pricing boundary that is not already represented by an applicable organisational Guardrail, AI may translate that boundary into an initiative-specific condition or constraint.

That condition or constraint must remain distinguishable from an organisational Guardrail.

Where an applicable organisational Guardrail already exists, AI may reference it but must not redefine its threshold, scope, configuration version or behavioural treatment.

Creation or modification of an organisational Guardrail requires the authorised governance process defined in GOV-023.

The user must review and explicitly apply the resulting structure.

10.8. AI-008 Structured Output Validation

AI-generated structured pricing work must pass the same product validation applied to human-created pricing work.

AI output must not bypass:

- required fields;
- formula validation;
- scope validation;
- guardrail evaluation;
- permissions;
- workflow rules.

10.9. AI-009 Analysis Assistance

AI may assist users in interpreting pricing analysis.

It may:

- compare scenarios;
- explain financial implications;
- highlight material differences;
- identify unusual outcomes;
- surface trade-offs;
- identify entities requiring closer inspection;

- summarise guardrail results.

10.10. AI-010 Deterministic Calculation Boundary

AI must not act as the authoritative calculation or Guardrail-evaluation engine for consequential pricing work.

Core financial calculations such as:

- gross margin;
- markup;
- price change;
- gross profit

must be produced by the deterministic analytical calculation layer defined in Section 3.5.

Deterministic evaluation of applicable organisational Guardrails must be performed under ANALYSIS-014 using the applicable governance-defined Guardrail configuration.

AI may explain or interpret financial calculations and Guardrail evaluation results, but it must not substitute its own arithmetic, infer a competing Guardrail result or replace system-calculated values.

Where the required inputs are unavailable or an authoritative calculation or Guardrail evaluation has not been produced, AI must not manufacture one and present it as system output.

10.11. AI-011 Scenario Assistance

AI may assist users in constructing alternative pricing scenarios.

It may suggest alternatives based on available information, such as:

- different price movements;
- different margin targets;
- different assumptions;
- different scope selections;
- alternative rule structures.

Suggested scenarios must remain exploratory until explicitly created or selected by a user.

10.12. AI-012 Risk and Inconsistency Detection

AI may identify potential issues including:

- contradictory assumptions;
- inconsistent rationale;
- missing supporting context;
- unusual pricing changes;
- incomplete proposal explanations;
- conflicts between stated objectives and proposed actions.

AI-generated risk identification must remain advisory unless the condition is independently enforced by a product guardrail or validation rule.

10.13. AI-013 Missing Information Detection

AI should help users identify information that may be required to progress pricing work.

It must distinguish between:

- information that is genuinely required by the system;
- information that may improve decision quality;
- optional contextual information.

AI must not present optional information as a system requirement.

10.14. AI-014 Collaboration Assistance

AI may assist with collaborative pricing work by:

- summarising discussion;
- identifying unresolved questions;
- synthesising stakeholder input;
- identifying conflicting positions;
- summarising requested changes;
- preparing review summaries.

AI must not falsely attribute statements or decisions to users who did not make them.

10.15. AI-015 Proposal Preparation

AI may assist users in preparing a Pricing Proposal by summarising:

- objective;
- proposed action;
- pricing scope;
- relevant economics;
- assumptions;
- guardrail status;
- supporting evidence;
- key risks;
- material changes.

The final submitted proposal must remain explicitly submitted by an authorised human user.

10.16. AI-016 Review Assistance

During review or approval, AI may help authorised users understand a proposal.

This may include:

- summarising the proposal;
- comparing it with the current state;
- explaining material assumptions;
- identifying changes from a previous version;
- summarising discussion;
- explaining applicable calculations.

AI must not determine the formal review or approval outcome.

10.17. AI-017 Historical Knowledge Retrieval

AI should be able to help authorised users locate and understand relevant previous pricing work.

It may retrieve context from accessible:

- completed Pricing Initiatives;
- previous proposals;

- historical pricing strategies;
- prior decisions;
- previous assumptions;
- recorded outcomes.

Retrieval must respect the invoking user's permissions.

10.18. AI-018 Historical Context Separation

AI must distinguish historical information from current pricing information.

A previous price, assumption or decision must not be represented as currently valid simply because it appears in historical records.

10.19. AI-019 Data Freshness Awareness

Where AI relies on pricing context with available timestamps or freshness information, it should preserve that distinction in its response.

AI must not represent manually entered, imported or historical information as live or real-time information unless the system actually provides that status.

10.20. AI-020 Evidence Awareness

Where AI uses workspace evidence to support its response, the user should be able to identify the relevant underlying pricing context or evidence where practical.

AI should not obscure the difference between:

- structured organisational data;
- manually supplied evidence;
- explicit assumptions;
- previous pricing records;
- AI inference.

10.21. AI-021 Uncertainty and Missing Basis

Where available information does not support a reliable conclusion, AI must indicate that limitation rather than inventing missing pricing facts.

AI must not fabricate:

- competitor prices;
- costs;
- demand figures;
- margins;
- exchange rates;
- customer behaviour;
- approval authority;
- organisational policy.

10.22. AI-022 Explicit Application of AI Output

AI-generated changes to structured pricing work must require an explicit user action such as:

- Apply;
- Insert;
- Create Scenario;
- Update Draft;
- Use as Starting Point.

Generating an AI response must not itself modify authoritative pricing work.

10.23. AI-023 AI Change Preview

Before applying a consequential AI-generated modification, users should be able to understand what will change.

Where AI modifies existing structured pricing work, the product should make relevant differences visible.

10.24. AI-024 AI Attribution

Applied AI-assisted content must remain attributable.

The system should preserve that:

- AI generated or suggested the content;
- a specific human user chose to apply it;
- the application occurred at a specific time.

The human user who applies the output remains responsible for progressing that work through applicable governance.

10.25. AI-025 AI Conversation Context

AI interactions associated with a Pricing Initiative should retain sufficient conversational context to support continuity during the active work.

However, important pricing assumptions, decisions or rules must not exist solely inside an AI conversation.

Consequential information must be applied to the appropriate structured pricing object before it becomes part of the formal pricing record.

10.26. AI-026 AI and Versioning

Applying AI-generated changes that materially alter pricing work must follow the same versioning rules as human changes.

AI assistance must not bypass Pricing Proposal versioning or any applicable repeat review, Approval or Policy Authorisation requirements.

10.27. AI-027 AI and Guardrails

AI may assist users in understanding applicable organisational Guardrails.

Where permitted by the user's access, AI may explain or summarise:

- the Guardrail definition;
- applicable scope;
- configured threshold or condition;
- applicable configuration version;
- ANALYSIS-014 evaluation result;
- GOV-025 behavioural treatment;
- the effect of the Guardrail on Proposal or workflow progression.

AI must consume authoritative Guardrail information from the applicable product records.

AI must not independently:

- create an organisational Guardrail through ordinary pricing work;

- determine Guardrail applicability where governance has not established it;
- redefine a Guardrail;
- modify a Guardrail threshold, operator, scope or behavioural treatment;
- calculate a competing Guardrail result;
- replace an ANALYSIS-014 evaluation with AI reasoning;
- infer Near Threshold where the configured Guardrail does not define the required proximity rule;
- represent Unable to Evaluate as Within Guardrail;
- override a Guardrail;
- ignore a Blocking treatment;
- claim that an exception or authorised progression path exists where none has been configured.

AI may identify a possible need for a new or changed Guardrail as an advisory observation, but that observation must not become organisational governance until an authorised user completes the applicable governance action.

Where AI converts user pricing intent into structured Builder content, a user-defined pricing boundary must remain an initiative-specific condition or constraint unless it references an existing organisational Guardrail.

AI therefore assists with interpretation and explanation while Guardrail definition, evaluation and behavioural consequence remain controlled by GOV-023, ANALYSIS-014 and GOV-025 respectively.

10.28. AI-028 AI and Approval Authority

AI has no approval authority.

AI cannot:

- approve;
- reject;
- request changes as a formal approver;
- provide policy authorisation;
- impersonate an approver.

Formal item-level Approval decisions require authorised human action.

Policy Authorisation may be established only through the configured non-AI policy-authorisation mechanism defined in FLOW-022 and FLOW-023.

10.29. AI-029 AI and Execution Authority

AI must not independently execute pricing actions in the MVP.

AI may assist an authorised user in understanding:

- what received execution authority;
- what needs to be implemented;
- applicable execution instructions.

Recording or confirming implementation requires an authorised human action.

10.30. AI-030 AI and Governance Administration

AI may explain existing workspace governance where the invoking user has access.

AI must not autonomously:

- grant permissions;
- assign commercial authority;
- modify approval limits;
- alter guardrails;
- activate policy autonomy;
- change workflow governance.

10.31. AI-031 Adversarial or Conflicting Content

Content supplied through:

- attachments;
- comments;
- imported data;
- manually entered evidence;
- external text

must be treated as business information, not as authority to override Owómidé's system rules, permissions or AI governance.

Instructions contained inside user-provided evidence must not override product-level governance.

10.32. AI-032 AI Failure Handling

Failure of an AI capability must not corrupt or block access to existing authoritative pricing records.

Users must remain able to access and continue supported non-AI workflow functions where the underlying task does not inherently require AI.

The MVP's system of record must not depend on an AI response being successfully generated.

10.33. AI-033 AI Feedback

Users should be able to indicate when AI output is:

- useful;
- incorrect;
- incomplete;
- inappropriate for the pricing context.

Where applicable, users should be able to discard AI output without affecting the underlying pricing work.

10.34. AI-034 AI Activity History

Consequential AI-assisted actions should contribute to relevant activity history.

The history should distinguish between:

- AI suggestion generated;
- AI output applied by a user;
- AI-assisted structured change;
- subsequent human modification.

Routine conversational prompts do not need to overload the formal audit trail unless they materially affect pricing work.

10.35. AI-035 AI Completeness Principle

AI in the MVP succeeds when it reduces the cognitive and administrative effort required to perform real pricing work while preserving human control, deterministic financial logic and organisational governance.

For any consequential AI-assisted pricing action, Owómidé must be able to answer:

What information was available to the AI?
What did the AI propose?
What did the user choose to apply?
What changed in the pricing work?
Did normal validation and governance still apply?
Who retained authority for the resulting decision?

AI must accelerate and improve pricing work without becoming an uncontrolled pricing decision-maker.

3.11 Execution and Post-Implementation Monitoring

11. EXECUTION AND POST-IMPLEMENTATION MONITORING

The MVP must preserve continuity between a pricing decision and its operational outcome.

Organisational decision authority is not the end of pricing work. Owómidé must record the exact Pricing Proposal version that became Approved or Authorised Within Policy, the pricing action thereby authorised, what was actually implemented, when implementation occurred, whether implementation matched that authorised decision baseline, and what happened after the change.

The MVP does not require automated publishing into external operational systems. Manual implementation outside Owómidé remains valid where the resulting execution is recorded inside the Pricing Initiative.

11.1. EXEC-001 Execution Eligibility

A pricing action may enter execution only after the Pricing Initiative has satisfied the execution-readiness gate defined in FLOW-030 and has entered Ready for Execution.

Execution must be bound to the exact controlled Pricing Proposal version that provides the current execution authority under PROP-021.

The applicable Proposal version must:

- have Pricing Proposal status Approved or Authorised Within Policy;
- remain the Current applicable Proposal version and valid for execution;
- be identifiable as the exact authorised decision baseline;
- retain the applicable decision snapshot;
- have a defined pricing scope and executable pricing action;
- satisfy applicable effective timing and execution conditions.

Before execution begins, the system must also verify that:

- the acting user possesses the required execution authority;
- no blocking workflow condition remains;
- no blocking governance condition remains;
- required implementation information is available for the applicable pricing action.

Failure of any required execution condition must prevent execution from beginning or continuing until the condition is appropriately resolved.

A Draft, Awaiting Approval, Changes Requested, Rejected, Superseded or Expired Proposal version must not provide execution authority.

The execution layer must not independently approve, policy-authorise, modify or reinterpret the Pricing Proposal that provides its execution authority.

11.2. EXEC-002 Ready for Execution State

When all execution conditions are satisfied, the Pricing Initiative must enter Ready for Execution.

The applicable Pricing Proposal must retain its Approved or Authorised Within Policy status and remain the exact controlled Proposal version providing execution authority.

The system must clearly display:

- authorised pricing action;
- applicable Pricing Proposal status;
- authorised Pricing Proposal version;
- affected pricing scope;
- authorised prices, pricing rule or pricing logic, as applicable;
- effective date or effective period;
- implementation owner;
- relevant implementation instructions;
- conditions attached to the applicable approval or policy authorisation.

Ready for Execution indicates that the Pricing Initiative is permitted to proceed into implementation.

It must not indicate that implementation has already occurred, modify the Pricing Proposal's decision status or create a new source of execution authority.

11.3. EXEC-003 Execution Ownership

An authorised user must be assignable as the implementation owner.

Execution ownership determines responsibility for carrying out, coordinating or recording implementation of the authorised pricing action.

Execution ownership does not itself grant authority to:

- modify the authorised Pricing Proposal version;
- change the authorised pricing action;
- change the authorised pricing scope;
- alter the decision snapshot;
- create approval or policy-authorisation authority.

Any material difference between the authorised decision baseline and the action intended for implementation must follow the applicable execution-variance and governance requirements.

11.4. EXEC-004 Execution Instructions

The authorised pricing action must provide enough structured information for the implementation owner to determine exactly what must be implemented.

Where applicable, execution instructions should identify:

- affected priceable entity or pricing scope;
- applicable location, channel, customer group or other pricing dimension;
- relevant current or baseline pricing state;
- authorised price, pricing value, pricing rule or pricing logic;
- effective date or effective period;
- temporary pricing period where applicable;
- authorised exceptions;
- implementation conditions;
- relevant operational instructions.

Execution instructions must derive from the exact controlled Pricing Proposal version providing execution authority.

The execution layer must not silently substitute later workspace values, another Scenario, another Proposal version or changed pricing logic for the authorised execution baseline.

11.5. EXEC-005 Manual External Execution

Where the actual price change occurs in an external system, authorised users must be able to record the implementation inside Owómidé.

External implementation may occur through systems such as:

- ERP;
- POS;
- marketplace;
- commerce platform;
- internal business system;
- another operational pricing channel.

Owómidé must not represent external execution as completed until an authorised user records or confirms it.

11.6. EXEC-006 Implementation Confirmation

An authorised Executor must be able to confirm that the pricing action has been implemented.

Confirmation must capture:

- implementing user;
- implementation timestamp;
- actual effective date;
- implementation status;
- actual implemented pricing state where applicable.

11.7. EXEC-007 Authorised and Implemented Value

Where the authorised pricing action changes a specific numerical price or other directly implementable pricing value, the system must allow the Executor to record the actual implemented value.

The system must preserve separately:

Authorised Value

and

Implemented Value

The Authorised Value must be derived from the exact controlled Pricing Proposal version providing execution authority.

The Implemented Value must represent what was actually implemented.

Recording the Implemented Value must not overwrite or modify the Authorised Value.

Where the Implemented Value differs materially from the Authorised Value, that difference must remain identifiable through the execution-variance requirements.

11.8. EXEC-008 Execution Variance

The system must identify where actual implementation differs from the authorised pricing action or execution baseline.

Relevant variance may include:

- different implemented price or pricing value;
- different pricing rule or logic;
- different affected scope;
- different location, channel or other pricing dimension;
- different effective date or period;
- omitted entities;
- additional entities;
- different promotional or temporary pricing period;
- unauthorised exception or condition.

Execution variance must remain visible within the Pricing Initiative and linked to the exact Pricing Proposal version that provided execution authority.

The existence of a variance must not modify the original authorised Proposal version or decision record.

Material execution variance must be treated according to EXEC-009.

11.9. EXEC-009 Material Execution Deviation

Where an actual or intended implementation materially differs from the authorised Pricing Proposal version or authorised decision baseline, the system must not treat that deviation as authorised by the existing approval or policy authorisation.

Where the material deviation is identified before implementation, the system must require either:

- correction of the intended implementation so that it matches the authorised decision baseline; or
- progression of the materially changed pricing action through the applicable Pricing Proposal and organisational decision process before implementation.

Where a material deviation is identified after implementation has occurred, the system must:

- preserve the actual implemented pricing state;
- identify the affected scope;
- preserve the implementation timestamp and responsible user;
- record the deviation as an Implementation Exception;
- preserve the difference between the authorised and implemented action;
- require appropriate remediation, follow-up pricing work or organisational decision treatment according to applicable policy.

An approval or policy authorisation attached to the original Pricing Proposal version must not be retrospectively extended or reinterpreted to authorise a materially different implemented action.

The execution layer must not independently authorise a material deviation.

11.10. EXEC-010 Execution Status and Partial Implementation

The MVP must maintain execution status separately from Pricing Proposal status and Pricing Initiative lifecycle state.

Supported execution statuses must include:

- Not Started;
- In Progress;
- Partially Implemented;
- Implemented;
- Implementation Exception.

Not Started indicates that implementation of the authorised pricing action has not begun.

In Progress indicates that implementation has begun but has not yet reached a completed implementation state.

Partially Implemented indicates that only part of the authorised pricing scope has been implemented.

Implemented indicates that the applicable authorised pricing action has been implemented across the required execution scope, subject to any separately recorded variance.

Implementation Exception indicates that implementation cannot validly continue or be represented as normally completed because of a material deviation, blocking condition, failed implementation or other consequential execution issue.

For pricing actions affecting multiple priceable entities, locations, channels or other pricing dimensions, the system must preserve enough component-level execution information to identify what has and has not been implemented.

Aggregate execution status must not conceal incomplete, failed or materially divergent implementation.

Execution status must not modify the Pricing Proposal's Approved or Authorised Within Policy status.

11.11. EXEC-011 Failed or Blocked Implementation

Where implementation cannot be completed, the Executor must be able to record:

- affected scope;
- failure or blocking reason;
- timestamp;
- relevant notes.

The initiative must remain unresolved until the execution state is appropriately addressed.

11.12. EXEC-012 Implementation Evidence

Users should be able to attach relevant evidence confirming execution.

Examples include:

- system export;

- screenshot;
- implementation report;
- internal confirmation;
- other supporting evidence.

Evidence must remain attached to the execution record.

11.13. EXEC-013 Execution History

Consequential execution events must be recorded in chronological history.

This includes:

- assignment;
- readiness for execution;
- implementation started;
- partial implementation;
- implementation confirmation;
- implementation failure;
- implementation variance;
- correction.

11.14. EXEC-014 Current Price Update

Where implementation is confirmed and the applicable organisation pricing record is maintained inside Owómidé, the system should allow the actual implemented selling price to establish or update the applicable Price Record.

The resulting Price Record must identify, where applicable:

- affected Priceable Entity;
- actual implemented price;
- currency;
- applicable pricing dimensions;
- actual effective date or timestamp;
- originating Pricing Initiative;
- authorised Pricing Proposal version;
- Execution Record;
- implementing or confirming user;

- source and provenance.

Where the implemented price becomes presently applicable to that exact pricing context, the resulting Price Record should become the Current Price in accordance with DATA-003.

Establishing the implemented price as Current Price must not overwrite the Price Record representing the previous Current Price.

Where the previous Current Price has an open-ended or overlapping effective period, establishing the implemented Price Record as the new Current Price must end the previous record's current applicability from the applicable new effective time.

This transition must preserve the previous Price Record and its historical period of applicability rather than rewriting the previous selling-price value.

The system must therefore be able to distinguish:

- the Price Record that applied before implementation;
- the effective transition point;
- the Price Record that applies after implementation.

Updating effective applicability to reflect that transition must not destroy the historical state that existed before the implemented price became effective.

The previous Price Record must remain historically preserved.

Where implementation affects only part of an authorised Pricing Scope, Current Price must be updated only for the Priceable Entities and pricing-dimension combinations actually confirmed as implemented.

Where the actual implemented price differs materially from the authorised pricing value, the system must preserve that difference through the applicable execution-variance requirements before treating the implemented value as an ordinary authorised implementation outcome.

A Current Price update must not silently modify:

- the authorised Pricing Proposal version;
- its submitted decision snapshot;
- the authorised pricing value;
- the historical current price used as the decision baseline.

Where implementation occurs outside Owómidé, the workspace must not represent the new value as Current Price until implementation has been recorded or confirmed through the applicable execution process.

The resulting Current Price must remain traceable to the implementation event that established it.

11.15. EXEC-015 Monitoring State

After implementation, a Pricing Initiative may enter **Monitoring**.

Monitoring exists to assess whether the pricing action produced the intended outcome and to preserve post-decision learning.

11.16. EXEC-016 Monitoring Period

Where relevant, users should be able to define a monitoring period or review date.

This may be based on:

- fixed date;
- number of days after implementation;
- promotional period;
- organisation-defined review point.

The MVP does not require continuous automated monitoring.

11.17. EXEC-017 Monitoring Metrics

Users must be able to record relevant post-implementation outcomes where information is available.

Supported outcome categories may include:

- sales;
- revenue;
- volume;
- gross margin;
- gross profit;
- customer response;

- commercial feedback;
- operational feedback;
- pricing exceptions.

11.18. EXEC-018 Baseline Comparison

Where sufficient baseline information is available, users should be able to compare post-implementation outcomes with the relevant pre-change position.

The system must clearly identify whether the comparison is based on:

- structured organisational data;
- imported data;
- manually entered information.

11.19. EXEC-019 Objective Assessment

Users should be able to record whether the initiative's original pricing objective was:

- Achieved;
- Partially Achieved;
- Not Achieved;
- Unable to Determine.

The assessment may include explanatory notes.

11.20. EXEC-020 Qualitative Outcome Recording

Monitoring must not require every pricing outcome to be expressed numerically.

Users must be able to record qualitative outcomes such as:

- customer resistance;
- improved competitiveness;
- distributor feedback;
- sales-team feedback;
- unexpected operational consequences;
- competitor response.

11.21. EXEC-021 Monitoring Data Provenance

Post-implementation information must preserve its available source and timestamp.

Manually entered monitoring information must not be presented as automatically collected operational data.

11.22. EXEC-022 AI Monitoring Assistance

AI may assist users in interpreting recorded post-implementation information.

AI may:

- summarise outcomes;
- compare outcomes with the initiative objective;
- identify notable changes;
- surface possible lessons;
- help prepare a closing summary.

AI must not fabricate missing performance data or claim causation that the available evidence does not support.

11.23. EXEC-023 Outcome Attribution Boundary

The MVP must distinguish between:

- observed outcome;
- user interpretation;
- AI interpretation.

A change in sales, revenue or margin following implementation must not automatically be represented as caused solely by the pricing action unless the evidence supports that conclusion.

11.24. EXEC-024 Follow-Up Pricing Work

Where monitoring indicates that further pricing action is required, an authorised user should be able to create a new Pricing Initiative using relevant context from the completed initiative.

The new initiative must remain a separate pricing record with its own:

- objective;
- versions;

- organisational decision records;
- execution history.

11.25. EXEC-025 Completion Readiness

An implemented initiative may be completed when its required operational obligations are resolved.

Depending on the initiative, completion may require:

- implementation finished;
- execution exceptions resolved;
- required monitoring information recorded;
- objective assessment completed.

Not every initiative must require an extended monitoring period before completion.

11.26. EXEC-026 Completion Summary

A completed Pricing Initiative should preserve a concise final summary sufficient to connect the original pricing objective with the organisational decision, actual implementation and recorded outcome.

The summary should contain, where applicable:

- original pricing objective;
- exact Pricing Proposal version that provided execution authority;
- whether that Proposal version was Approved or Authorised Within Policy;
- authorised pricing action;
- actual implemented pricing action or state;
- significant execution variances or Implementation Exceptions;
- relevant monitored outcomes;
- final objective assessment;
- final Pricing Initiative status.

The completion summary must distinguish what was authorised from what was actually implemented.

It must not overwrite or simplify away material differences preserved in the Proposal, execution or monitoring records.

11.27. EXEC-027 Historical Execution Integrity

Subsequent pricing changes must not rewrite the execution record of an earlier initiative.

Historical records must continue to show what was implemented at that point in time.

11.28. EXEC-028 Execution Permission Enforcement

Only users with appropriate execution authority may confirm consequential implementation.

A user who can view or approve a Pricing Proposal must not automatically gain execution authority.

11.29. EXEC-029 Execution Auditability

For every consequential implemented pricing action, Owómidé must preserve enough information to determine:

- which exact Pricing Proposal version provided execution authority;
- whether that Proposal version was Approved or Authorised Within Policy;
- what exact pricing action and scope were authorised;
- who was responsible for implementation;
- what was actually implemented;
- when implementation occurred;
- whether implementation matched the authorised decision baseline;
- what execution variance or Implementation Exception occurred, where applicable;
- what happened after implementation.

Execution auditability must preserve the distinction between organisational decision authority and actual implementation.

A later Pricing Proposal, pricing change or workspace update must not rewrite the execution basis or actual implementation record of the earlier action.

11.30. EXEC-030 Execution and Monitoring Completeness Principle

The pricing lifecycle is not complete merely because a Pricing Proposal becomes Approved or Authorised Within Policy.

The MVP must preserve an intelligible chain from:

Proposed Pricing Action → Organisational Decision Authority → Actual Implementation → Observed Outcome

For every consequential pricing action, the organisation must be able to distinguish:

- what was proposed;
- which exact Pricing Proposal version received execution authority;
- whether that authority resulted from approval or policy authorisation;
- what was actually implemented;
- whether implementation differed from the authorised decision baseline;
- what outcome was subsequently recorded.

Proposal decision status, execution status and observed outcome must remain separate concepts.

The system must not imply that authorisation guarantees implementation or that implementation guarantees the intended commercial outcome.

3.12 Versioning, Audit Trail and Pricing Knowledge

12. VERSIONING, AUDIT TRAIL AND PRICING KNOWLEDGE

The MVP must preserve the history of consequential pricing work so that organisations can reconstruct how a pricing decision developed, who influenced it, which version was authorised, what was implemented and what was learned afterward.

Historical integrity must not depend on users maintaining separate spreadsheets, email trails or personal records.

12.1. HIST-001 Persistent Pricing Record

Every Pricing Initiative must maintain a persistent historical record containing the relevant:

- objective;
- pricing scope;
- pricing context;
- assumptions;
- pricing logic;
- analysis;
- scenarios;
- proposals;
- collaboration;
- reviews;
- organisational decision records, including approvals and policy authorisations;
- execution;
- monitoring;
- lifecycle events.

Closing or completing an initiative must not remove this record.

12.2. HIST-002 Controlled Version Historical Integrity

Working drafts may change continuously.

When a Pricing Proposal is submitted, the system must preserve the exact submitted decision snapshot and decision-relevant contents associated with that controlled Proposal version.

Permitted non-material post-submission changes under PROP-018 may update only the administrative or descriptive elements allowed by that requirement and must remain separately attributable and auditable.

Such changes must not rewrite the preserved submitted decision snapshot, material pricing content, decision basis or organisational decision history of the controlled Proposal version.

Where a Proposal version subsequently receives organisational decision authority, later validity changes, execution activity, annotations or permitted administrative corrections must be represented through their applicable records or auditable events rather than by rewriting the historical decision basis of that Proposal version.

12.3. HIST-003 Proposal Version Identifier

Each controlled Pricing Proposal version must have a unique version identifier within its Pricing Initiative.

The system must distinguish between:

- the persistent Pricing Proposal identifier;
- the identifier of each controlled Proposal version;
- the Proposal status defined in PROP-012;
- the Proposal version validity defined in PROP-013.

Users must be able to distinguish controlled versions such as Version 1, Version 2 and Version 3 without confusing version numbering with Proposal status or validity.

The system must identify which Proposal version, if any, is Current in accordance with PROP-013.

`Active` must not be introduced as an additional Proposal version validity state.

Previous Proposal versions must remain identifiable and historically retrievable after another version becomes Current.

12.4. HIST-004 Controlled Proposal Version Creation History

When a new controlled Pricing Proposal version is created following a material post-submission change in accordance with PROP-017, the system must preserve the version-creation event as part of the Pricing Initiative's historical record.

The historical record must identify:

- the previous Proposal version;
- the newly created Proposal version;
- the user responsible for the revision;
- the version-creation timestamp;
- the reason or originating change where available;
- the relationship between the previous and new Proposal versions.

Creation of a new controlled Proposal version must not overwrite, modify or reinterpret the contents, status, organisational decision records or decision history of the previous version.

The historical layer must record version creation but must not independently redefine what constitutes a material Proposal change. Material-change rules are governed by PROP-017.

A later change to Proposal Version Validity under PROP-019 or PROP-020 must not be treated as rewriting the historical Proposal Status or organisational decision recorded for that Proposal version.

For example, an Approved or Authorised Within Policy Proposal version may later become Superseded or Expired while preserving the original Proposal Status and organisational decision that occurred for that version.

12.5. HIST-005 Previous Version Preservation

Creating a new version must not overwrite the previous version.

Users with appropriate access must be able to retrieve previous versions and determine:

- what that version contained;
- when it was created;
- who created or submitted it;
- what decision was made against it.

12.6. HIST-006 Version Comparison

The MVP should allow users to compare relevant controlled versions of pricing work.

Comparison should identify material changes such as:

- price changes;

- scope changes;
- assumption changes;
- pricing-rule changes;
- analysis changes;
- guardrail-state changes.

Users should not have to manually compare historical records to determine what changed between submissions.

12.7. HIST-007 Decision Authority Binding

Every approval or policy authorisation must remain permanently associated with the exact controlled Pricing Proposal version against which that decision authority was established.

Approval of one Proposal version must never be represented as approval of another Proposal version.

Policy authorisation of one Proposal version must never be transferred, inherited or represented as policy authorisation of another Proposal version.

Where a materially revised Proposal creates a new controlled version, previous approval or policy-authorisation records must remain historical records attached only to the earlier Proposal version.

Historical decision authority must remain consistent with PROP-021 and must not be rewritten by later Proposal, workflow, governance or execution changes.

12.8. HIST-008 Historical Preservation of Proposal Decision Snapshot

For every submitted Pricing Proposal version, the system must preserve the complete controlled decision snapshot established under PROP-011 as part of the Pricing Initiative's historical record.

The historical record must preserve the Proposal snapshot exactly as it existed when that version was submitted, including its relationships to the underlying pricing context, analysis, assumptions, evidence, guardrail evaluation and other decision-relevant source objects.

Subsequent changes to:

- current prices;

- costs or other financial inputs;
- pricing context;
- Pricing Builder logic;
- assumptions;
- analysis;
- evidence;
- guardrails;
- workflow or governance configuration;
- other workspace data

must not modify, recalculate or reinterpret the historical Proposal decision snapshot.

Where a referenced source object changes after submission, the historical Proposal version must continue to resolve to the version or value that formed part of its original decision snapshot.

Historical preservation must not independently redefine the contents of the Proposal decision snapshot. The canonical snapshot contract is governed by PROP-011.

12.9. HIST-009 Activity Timeline

Every Pricing Initiative must contain a chronological activity timeline.

Relevant events should include:

- initiative creation;
- scope changes;
- significant edits;
- comments;
- assignments;
- evidence additions;
- scenario creation;
- review submission;
- proposal submission;
- requested changes;
- approvals;
- policy authorisations;
- rejections;
- escalation;

- execution events;
- monitoring updates;
- completion;
- cancellation.

12.10. HIST-010 Activity Attribution

Each consequential activity event must identify:

- actor;
- action;
- timestamp;
- affected object;
- relevant version where applicable.

System-generated events must be distinguishable from human actions.

12.11. HIST-011 AI Attribution

Where AI-assisted content materially affects pricing work, history must preserve:

- that AI assistance was involved;
- which user applied the output;
- when the change occurred;
- which pricing object was affected.

AI must not appear as the accountable human decision-maker.

12.12. HIST-012 Administrative History

Consequential administrative changes affecting pricing governance must remain historically available.

Examples include:

- role changes;
- permission changes;
- approval-authority changes;
- workflow changes;
- guardrail changes;

- cost-access changes;
- policy-authorisation configuration changes.

12.13. HIST-013 Historical Governance Context

Completed pricing decisions must retain enough information to determine which governance rules applied at the time.

Changing current organisational configuration must not rewrite the governance context of earlier decisions.

12.14. HIST-014 Historical Identity Preservation

Where a user later leaves, is suspended or changes roles, their previous actions must remain attributable to their historical identity.

The system must not replace historical actors with generic labels that destroy accountability.

12.15. HIST-015 Audit Record Integrity

Formal audit records must not be silently editable or deletable by ordinary users.

Where administrative correction is necessary, the correction must itself create an auditable event rather than rewriting the original history.

12.16. HIST-016 Searchable Pricing History

Authorised users must be able to search historical pricing work.

Search should support relevant criteria such as:

- Pricing Initiative;
- product or SKU;
- category;
- owner;
- initiative type;
- status;
- decision date;
- implementation date;
- proposal outcome.

Search results must respect user permissions and scope.

12.17. HIST-017 Historical Filtering

Users should be able to filter pricing history by relevant dimensions including:

- completed;
- rejected;
- cancelled;
- product or category;
- date range;
- location;
- channel;
- initiative type;
- responsible user.

12.18. HIST-018 Historical Initiative View

A historical Pricing Initiative must remain understandable as a coherent record.

Users should be able to determine:

- why the initiative existed;
- what was considered;
- what was proposed;
- what changed;
- what organisational decision was made, including whether the applicable Pricing Proposal was Approved or Authorised Within Policy;
- what was implemented;
- what outcome was recorded.

12.19. HIST-019 Organisational Pricing Knowledge

Completed pricing work should become reusable organisational knowledge.

Relevant previous work may provide context for:

- future Pricing Initiatives;
- pricing strategies;
- assumptions;

- scenarios;
- decision rationale;
- recurring pricing situations.

12.20. HIST-020 Reuse Without Authority Transfer

Users may reuse appropriate structures or context from historical pricing work.

Reused content must create new working material.

Historical:

- Approval records;
- Policy Authorisation records;
- execution status;
- proposal validity

must not transfer to new pricing work.

12.21. HIST-021 AI Historical Retrieval

AI may help authorised users locate and summarise relevant historical pricing work.

AI retrieval must respect:

- organisation boundaries;
- user access scope;
- sensitive-data permissions;
- historical context.

AI must distinguish historical decisions from current pricing instructions.

12.22. HIST-022 Decision Rationale Preservation

The system must preserve enough structured and contextual information to explain why a consequential pricing decision was made.

Rationale may include:

- stated objective;
- assumptions;

- supporting evidence;
- analysis;
- stakeholder input;
- proposal explanation;
- Approval comments or Policy Authorisation evaluation information.

A final price alone is not a sufficient historical record.

12.23. HIST-023 Record Retention

Pricing history must remain available according to the organisation's supported retention policy.

The MVP should default toward preserving completed pricing records rather than automatic deletion.

12.24. HIST-024 Exportable Historical Record

Authorised users should be able to export relevant historical pricing records where needed for:

- audit;
- management review;
- internal reporting;
- operational reference.

Exports must respect data-access restrictions.

12.25. HIST-025 Audit Search

Users with appropriate audit authority should be able to inspect activity by relevant dimensions such as:

- user;
- action type;
- Pricing Initiative;
- proposal;
- date range.

12.26. HIST-026 System Event Recording

System-enforced events that materially affect consequential pricing work should be recorded where relevant.

Examples include:

- creation of a new controlled Pricing Proposal version following a material post-submission change;
- policy-authorisation evaluation where the result materially affects Proposal progression;
- guardrail evaluation that blocks, escalates or otherwise materially affects progression;
- Pricing Proposal expiration;
- workflow escalation;
- prevention of execution or operational export because current execution authority is invalid;
- permission-based action denial where organisational audit policy requires it.

A system-generated event must identify the affected pricing object and relevant version where applicable.

System-event history must record what occurred without independently redefining the underlying Proposal, workflow, governance, guardrail, execution or permission rule that caused the event.

Historical approval or policy-authorisation records must not be described as deleted or retrospectively invalidated merely because a later Proposal version is created. Their authority remains bound to the exact Proposal version against which the original decision was established.

12.27. HIST-027 Record Consistency

Historical records displayed in different areas of Owómidé must refer to the same underlying event and version state.

The product must not maintain conflicting histories for the same pricing decision.

12.28. HIST-028 Pricing Knowledge Boundary

The MVP's pricing-knowledge capability is focused on preserving and retrieving the organisation's own pricing work.

The MVP is not required to provide a broad external pricing-knowledge database or automatically generated market-intelligence repository.

12.29. HIST-029 Historical Reconstruction Principle

For any completed or consequential Pricing Initiative, an authorised user should be able to reconstruct:

What triggered the pricing work?
What information was available?
What assumptions were made?
What alternatives were considered?
What changed during development and review?
What exact Pricing Proposal version was submitted, and what organisational decision was made against it, including Approved, Authorised Within Policy, Changes Requested or Rejected?
Who made each consequential decision?
What was implemented?
What outcome was recorded?

If this cannot be reconstructed from Owómidé, the pricing history is incomplete.

3.13 Notifications, Work Queues and Visibility

13. NOTIFICATIONS, WORK QUEUES AND VISIBILITY

The MVP must make pricing work requiring attention visible to the appropriate users without requiring them to manually inspect every Pricing Initiative.

Notifications should support action and awareness around pricing work, while the workspace itself remains the authoritative source of current state.

13.1. NOTIF-001 Personal Work Queue

Every active user should have a personal work view containing pricing work that currently requires or may require their attention.

This may include initiatives where the user is:

- owner;
- collaborator;
- reviewer;
- approver;
- assignee;
- implementation owner;
- mentioned;
- responsible for monitoring activity.

13.2. NOTIF-002 Action Required Separation

The system must distinguish between information that is merely visible to a user and work that requires an explicit action from that user.

Examples of action-required items include:

- assignment due;
- review requested;
- approval requested;
- requested clarification;
- execution assigned;
- monitoring input required.

13.3. NOTIF-003 Workspace-Level Visibility

Authorised users must be able to view relevant organisation-level pricing activity.

The workspace should provide visibility into categories such as:

- active Pricing Initiatives;
- initiatives requiring attention;
- pending reviews;
- pending approvals;
- ready-for-execution work;
- implementation in progress;
- monitoring activity;
- recently completed initiatives.

Visibility must respect the user's role and scope.

13.4. NOTIF-004 Pricing Initiative Status Visibility

Pricing Initiative listings must display enough information for users to understand current state without opening every initiative.

Relevant information should include:

- initiative title;
- initiative type;
- owner;
- pricing scope summary;
- lifecycle state;
- urgency;
- current responsible party;
- next required action;
- target or effective date where applicable.

13.5. NOTIF-005 Notification Events

The MVP must generate notifications for consequential events where user awareness or action is required.

These should include, where relevant:

- user assignment;
- mention;
- review request;
- approval request;
- changes requested;
- proposal rejection;
- proposal approval;
- proposal policy authorisation;
- escalation;
- upcoming due date;
- overdue action;
- execution assignment;
- implementation issue;
- monitoring assignment.

13.6. NOTIF-006 Notification Recipient

Notifications must be sent only to users relevant to the event.

The system must determine recipients based on:

- assignment;
- workflow responsibility;
- role;
- scope;
- mention;
- ownership;
- organisational configuration.

A notification must never provide an unauthorised user access to protected pricing information.

13.7. NOTIF-007 Notification Context

Every notification must provide enough context for the recipient to understand:

- what happened;
- which Pricing Initiative is affected;
- why the notification was generated;

- whether action is required.

Where applicable, the notification should identify the relevant proposal, assignment or workflow stage.

13.8. NOTIF-008 Direct Navigation

A user selecting a notification must be taken to the relevant authorised context inside Owómidé.

The user should not need to manually search for the associated Pricing Initiative.

13.9. NOTIF-009 In-Product Notifications

The MVP must support in-product notifications.

Notifications must have at least:

- unread;
- read

states.

Users should be able to mark notifications as read.

13.10. NOTIF-010 External Notification Boundary

Email notifications may be supported for important workflow events where needed for pilot adoption and timely action.

The MVP is not required to support:

- SMS;
- WhatsApp;
- Slack;
- Microsoft Teams;
- broad third-party notification integrations.

These must not become dependencies for the core pricing workflow.

13.11. NOTIF-011 Notification and Authority Separation

Receiving a notification does not grant authority to act.

A user may receive awareness of an event while still lacking permission to:

- edit;
- review;
- approve;
- execute.

Protected actions must continue to enforce normal permissions.

13.12. NOTIF-012 Pending Approval Queue

Users with approval authority must have a clear view of proposals currently awaiting their decision.

Each approval item should show relevant information such as:

- Pricing Initiative;
- proposal version;
- submitting user;
- submitted date;
- urgency;
- pricing scope;
- current workflow stage;
- approval deadline where applicable.

13.13. NOTIF-013 Review Queue

Users responsible for reviews must be able to identify:

- review requests assigned to them;
- review status;
- due date where applicable;
- initiative urgency.

13.14. NOTIF-014 Execution Queue

Authorised Executors must be able to identify pricing actions that are:

- Ready for Execution;

- assigned to them;
- partially implemented;
- blocked;
- overdue.

13.15. NOTIF-015 Owner Visibility

Pricing Initiative owners must be able to identify where their active initiatives are blocked or awaiting another stakeholder.

This should include relevant states such as:

- awaiting information;
- awaiting review;
- awaiting approval;
- awaiting execution;
- overdue assignment.

13.16. NOTIF-016 Urgency Visibility

High and Urgent Pricing Initiatives must be visually distinguishable from normal-priority work.

Urgency should influence ordering and prominence without changing underlying governance requirements.

13.17. NOTIF-017 Due Dates

Where pricing work has a defined deadline, relevant work views must display that deadline.

The system should identify work that is:

- upcoming;
- due;
- overdue.

13.18. NOTIF-018 Escalation Visibility

Where an escalation occurs, relevant users must be able to identify:

- what was escalated;
- why escalation occurred;

- previous responsible party;
- current responsible party;
- resulting action required.

13.19. NOTIF-019 Completed Work Visibility

Recent completed Pricing Initiatives should remain accessible from the workspace without appearing as outstanding work.

Completion must remove resolved tasks from active action queues while preserving historical access.

13.20. NOTIF-020 Read Versus Resolved State

Reading a notification must not mark the underlying business action as completed.

For example:

- reading an approval notification does not approve the proposal;
- reading an assignment notification does not complete the assignment;
- reading an execution notification does not confirm implementation.

Notification state and workflow state must remain separate.

13.21. NOTIF-021 Duplicate Notification Control

The system should avoid generating excessive duplicate notifications for the same unchanged condition.

Repeated reminders may be generated where action remains overdue, but they should be bounded and purposeful.

13.22. NOTIF-022 Notification Preference Boundary

The MVP may allow users to configure limited notification preferences for non-critical events.

Users must not be able to disable system-critical governance or security notifications where organisational policy requires them.

13.23. NOTIF-023 Access Revocation

If a user's access to relevant pricing work is removed, future notifications must respect the new access state.

Previously generated notifications must not provide a path to restricted content.

13.24. NOTIF-024 Workspace Filtering

Workspace-level work views should support filtering by relevant dimensions such as:

- status;
- owner;
- initiative type;
- urgency;
- category;
- product;
- location;
- channel;
- responsible participant;
- date range.

Filtering must respect user access scope.

13.25. NOTIF-025 Workspace Search

Users must be able to search pricing work they are authorised to access.

Search should support relevant identifiers such as:

- Pricing Initiative title;
- product or SKU;
- category;
- proposal identifier;
- owner.

13.26. NOTIF-026 Action Count Visibility

The workspace should provide a clear count of outstanding items requiring the current user's action.

Counts must be based on actual unresolved workflow responsibilities rather than general activity volume.

13.27. NOTIF-027 Notification History

Users should be able to access a recent history of their relevant notifications.

The notification history is not a substitute for the Pricing Initiative audit trail.

Consequential historical events must remain recorded in the underlying pricing record regardless of notification retention.

13.28. NOTIF-028 Authoritative Record Principle

Notifications, badges and work queues are navigation, visibility and attention-management mechanisms. They must reflect authoritative pricing records rather than independently define business state.

The authoritative source for each type of state must remain its underlying pricing object or record:

- the Pricing Initiative for Initiative lifecycle state, ownership, scope and overall progression;
- the Pricing Proposal for Proposal status, Proposal version validity and the applicable controlled decision package;
- workflow, approval and policy-authorisation records for review progress, approval progress, formal approval actions and policy-authorisation evaluations;
- the Execution Record for execution status, implementation progress and actual implemented action;
- the audit and historical record for consequential event and decision history.

Notifications, badges, queues and summary views must derive their displayed state from these authoritative records and must not create, redefine or silently override them.

Where different states are displayed together, the interface must preserve their distinction rather than collapse them into a single generic status.

A notification must never become the only record that a consequential event occurred.

13.29. NOTIF-029 Work Visibility Completeness Principle

For any active user, Owómidé should make it possible to answer:

What pricing work requires my attention?
Why does it require my attention?
How urgent is it?
What action am I expected to take?
When is it due?
Where do I perform that action?

For an authorised manager or initiative owner, the system should also make it possible to answer:

What active pricing work is blocked, where is it blocked, and who currently owns the next action?

3.14 Data Export and External Operational Handoff

14. DATA EXPORT AND EXTERNAL OPERATIONAL HANDOFF

The MVP must allow authorised pricing work to move from Owómidé into external business or productivity systems through supported integrations, structured exports and operational handoff mechanisms.

Owómidé may provide bounded integrations with selected external systems where direct connectivity materially reduces pricing-workflow or implementation friction.

The availability of a specific connector must be determined by supported MVP capabilities and validated customer requirements.

The core pricing workflow must remain usable without requiring broad integration coverage or automatic execution into an external operational system.

Owómidé must preserve the distinction between:

Transferring, synchronising or exporting an authorised pricing action

and

Confirming that the action was actually implemented.

Transfer, synchronisation or export alone must not be treated as implementation unless a supported external integration provides a verified implementation result that Owómidé can associate with the exact authorised pricing action.

14.1. EXPORT-001 Structured Pricing Export

Authorised users must be able to export supported pricing information from Owómidé in a structured format.

The MVP must support CSV export for applicable tabular pricing data.

14.2. EXPORT-002 Authorised Action Export

Pricing actions intended for operational implementation must be exportable from the exact approved or policy-authorised proposal version.

The export must not silently use later draft values or current workspace values that differ from the authorised decision.

14.3. EXPORT-003 Execution Export Content

Where applicable, an execution-oriented export should include:

- Pricing Initiative identifier;
- proposal identifier and version;
- Priceable Entity identifier;
- Priceable Entity name;
- Priceable Entity type;
- applicable category;
- location;
- channel;
- other relevant pricing dimensions;
- Current Price or other pricing baseline preserved in the exact authorised Proposal version's decision snapshot, where applicable and permitted;
- authorised price, pricing value, pricing rule or pricing logic, as applicable;
- currency;
- effective date;
- authorised exceptions;
- implementation notes where applicable.

The output must contain enough information for the receiving operational team to identify what should change.

For execution-oriented exports affecting multiple Priceable Entities, each exported pricing instruction must remain attributable to the applicable Priceable Entity and relevant pricing dimensions.

A category, product group or other grouping selector must not replace the Priceable Entity identifier required for operational implementation unless the receiving operational system explicitly implements pricing at that same directly priceable object level.

14.4. EXPORT-004 Bulk Export

The MVP must support export of pricing actions affecting multiple products or other priceable entities.

Bulk export must preserve entity-level results and exceptions.

14.5. EXPORT-005 External Identifiers

Where an organisation maintains external identifiers such as:

- ERP product code;
- SKU;
- POS identifier;
- marketplace listing identifier;
- internal reference code,

those identifiers should be available in operational exports where configured.

This reduces manual mapping during implementation.

14.6. EXPORT-006 Export Permission

Only users with appropriate export permissions may export protected pricing information.

Export authority must respect:

- organisation membership;
- role;
- resource;
- pricing scope;
- sensitive-data permissions.

14.7. EXPORT-007 Restricted Cost Data

Cost and sensitive financial information must be excluded from exports where the exporting user does not have permission to access it.

Export functionality must not bypass normal information-access controls.

14.8. EXPORT-008 Export Type Separation

The system must distinguish between exports created for different purposes.

Relevant categories may include:

- pricing-context export;
- analysis export;
- proposal export;
- authorised-action execution export;
- historical or audit export.

An exploratory Scenario export must not be represented as an authorised execution instruction.

14.9. EXPORT-009 Proposal Status, Validity and Execution Status Visibility

Where an export contains Pricing Proposal or execution information, the system must preserve the distinction between:

- Pricing Proposal Status;
- Pricing Proposal Version Validity;
- Execution Status.

Where Pricing Proposal Status is included, the exported value must use the canonical Proposal statuses defined in PROP-012:

- Draft;
- Awaiting Approval;
- Changes Requested;
- Rejected;
- Approved;
- Authorised Within Policy.

Where Pricing Proposal Version Validity is included, the exported value must use the canonical validity states defined in PROP-013:

- Current;
- Superseded;
- Expired.

Proposal Version Validity must not be merged into or represented as Pricing Proposal Status.

Where execution information is included, it must be represented separately using the applicable execution states defined in EXEC-010:

- Not Started;
- In Progress;
- Partially Implemented;
- Implemented;
- Implementation Exception.

An export must not represent a Pricing Proposal as Implemented because implementation is an operational execution state rather than a Pricing Proposal status.

An Approved or Authorised Within Policy Proposal version that is Superseded or Expired must preserve both pieces of information rather than replacing its historical Proposal status with its current validity state.

Exported status information must remain consistent with the authoritative Proposal and execution records inside Owómidé.

14.10. EXPORT-010 Unauthorised Execution Protection

The system must not allow a Pricing Proposal without current execution authority to be exported or handed off in a way that represents it as authorised for implementation.

A Proposal may provide execution authority only where the applicable controlled Proposal version:

- is Approved or Authorised Within Policy;
- remains Current and valid for execution;
- satisfies the applicable execution-readiness requirements.

Draft, Awaiting Approval, Changes Requested, Rejected, Superseded or Expired Proposal versions must not be represented through an execution-oriented export as currently authorised pricing actions.

Analytical, Draft, historical or other non-execution exports may still be permitted where the user's permissions allow, but their purpose and non-authorised execution status must remain explicit.

Export functionality must not independently create, infer or extend execution authority.

14.11. EXPORT-011 Version Identification

Exports of controlled pricing work must identify the relevant proposal or pricing-work version.

This allows the organisation to determine exactly which decision the exported output represents.

14.12. EXPORT-012 Export Timestamp

Every consequential export must record when the export was generated.

The exported output should also include a generation timestamp where operationally appropriate.

14.13. EXPORT-013 Export Attribution

Consequential exports must be attributable to the user who generated them.

The system must preserve:

- exporting user;
- timestamp;
- export type;
- related Pricing Initiative;
- proposal version where applicable.

14.14. EXPORT-014 Export Audit Event

Generation of an execution-oriented or sensitive pricing export must create an auditable event within the relevant historical record.

Routine low-risk exports may follow the organisation's supported audit policy.

14.15. EXPORT-015 Export After Proposal Change

Where an authorised Pricing Proposal version is subsequently superseded following a material change, previous exports must remain historical records but must not be represented as reflecting or authorising the revised Proposal version.

A new authorised version requires a new execution export.

14.16. EXPORT-016 Expired Pricing Action

Where a proposal or pricing action has expired, the system must prevent it from being exported as currently valid execution authority.

Historical export remains permissible where authorised and clearly labelled as historical.

14.17. EXPORT-017 Effective-Date Visibility

Execution-oriented exports must preserve the intended effective date or effective period where applicable.

The system must not assume that the export generation date is the pricing effective date.

14.18. EXPORT-018 Human-Readable Handoff

In addition to structured data, the MVP should provide an understandable summary of the authorised action for the person responsible for implementation.

The handoff should make clear:

- what must change;
- where it applies;
- when it becomes effective;
- which version was authorised;
- any relevant exceptions or conditions.

14.19. EXPORT-019 External Operational Handoff State

Where an authorised pricing action is handed to an external implementation process, the system should be able to record that the action has been Exported or Handed Off for Execution.

This state must identify:

- handoff timestamp;
- responsible user;
- affected proposal version;
- implementation owner where applicable.

14.20. EXPORT-020 Handoff Is Not Implementation

Marking pricing work as exported or handed off must not automatically move the Pricing Initiative to Implemented.

Implementation requires the separate confirmation defined in Section 3.11 Execution and Post-Implementation Monitoring, including EXEC-006 Implementation Confirmation.

14.21. EXPORT-021 Implementation Reference

When implementation occurs outside Owómidé, authorised users should be able to record an external implementation reference where available.

Examples include:

- ERP change reference;
- internal ticket number;
- batch identifier;
- marketplace update reference.

The MVP must not require an external reference where the organisation does not use one.

14.22. EXPORT-022 Exported Versus Implemented Comparison

Where an execution export exists, the system should preserve the relationship between:

Authorised Pricing Action → Exported/Handoff Action → Actual Implemented Action

This allows later identification of execution discrepancies.

14.23. EXPORT-023 Re-Export

Authorised users may regenerate an export for the same valid proposal version where operationally necessary.

Each consequential export event should remain attributable.

Re-exporting must not create a new Proposal version or new organisational decision authority by itself.

14.24. EXPORT-024 Data Formatting

Exports must use consistent:

- column definitions;
- currencies;
- numeric formats;
- dates;
- identifiers.

The system must avoid ambiguous representations that could cause operational pricing errors.

14.25. EXPORT-025 Missing Operational Identifier

Where a pricing action lacks an external identifier required by the organisation's implementation process, the system should surface the missing value before operational export where that field has been configured as required.

The system must not invent external identifiers.

14.26. EXPORT-026 Export Validation

Before generating an execution-oriented export, the system must validate that:

- the proposal has valid execution authority;
- the proposal version is current and identifiable;
- required implementation fields are present;
- affected scope is defined;
- applicable effective dates are valid;
- no blocking execution condition remains.

14.27. EXPORT-027 Historical Export

Authorised users must be able to export relevant historical pricing records for legitimate purposes such as:

- internal review;
- management reporting;
- audit;
- operational reference.

Historical exports must preserve original decision context rather than recalculate using current workspace values.

14.28. EXPORT-028 Bounded External Integration

The MVP must support bounded integration with selected external systems where those integrations materially improve the ability to exchange pricing context or authorised pricing work with the organisation's existing operating environment.

Supported integrations may include selected:

- spreadsheet and productivity systems;
- ERP platforms;
- commerce or marketplace platforms;
- other business systems required by validated MVP customers.

An integration may support inbound data exchange, outbound authorised pricing handoff or both, according to the capabilities of the supported connector.

The MVP is not required to provide broad connector coverage, universal bidirectional synchronisation or autonomous execution across an organisation's technology stack.

Where a native connector is unavailable, the customer must remain able to complete the core Owómidé pricing workflow through supported manual entry, structured import, export and operational handoff mechanisms.

Specific integrations must be prioritised according to validated customer and pilot requirements rather than treated as universal MVP dependencies.

14.29. EXPORT-029 External System Authority

Where the operational system remains the organisation's system of record for live prices, Owómidé must not falsely claim that an exported pricing action has changed that system.

Owómidé records the pricing decision and its execution status based on the information available within the MVP.

14.30. EXPORT-030 Operational Handoff Completeness Principle

For an authorised pricing action leaving Owómidé for external execution, the MVP must make it possible to answer:

What exactly was authorised?
Which proposal version did it come from?
Which entities and prices were included?
When should the change take effect?
Who exported or handed it off?
Who was responsible for implementation?
Was it subsequently confirmed as implemented?
Did the implemented result differ from the authorised action?
